

GENERAL DATA

Population, income and energy consumption in Italy

Figure 1

Gross domestic electricity consumption
Gross domestic energy consumption
Gross domestic product at market prices
Resident population at mid-year

Resident population at mid-year is calculated as the mean of the values at 31 December of the year considered and of the preceding year.

Gross domestic product at market prices is the value of final goods and services produced by the economy in the reference year, gross of provisions for depreciation and of indirect taxes.

Gross domestic consumption of energy represents the sum of the quantities of primary sources produced, primary and secondary sources imported and the variation of inventories of primary and secondary sources held by producers and importers, less the quantities of exported primary and secondary sources.

Gross domestic electricity consumption represents the sum of gross electricity production and net electricity imports. It is defined as net of pumping if the electricity produced by pumping in hydro plants is not included.

Final energy consumption consists of gross domestic energy consumption, less the consumption by the energy sector (the latter including the related inventory variations).

Gross electricity production by a group of power plants in a given period is the sum of the quantities of electricity produced, measured at the generator terminals.

(1) Revised figure.

(2) Annual series resulting from the General Revision of National Accounts carried out by Istat. Figures linked to the 2005 benchmark year.

(3) The conversion into toe of hydro, geothermal energy and net imports of electricity was calculated on the basis of a conventional average gross heat rate in conventional thermal power plants equivalent to 2,200 kcal/kWh.

SOURCES: General report on the Economic Situation of the Country,
"National Energy Balance".
