## New Foreword

On October 1, 2001 Axiom was withdrawn from the market and ended life as a commercial product. On September 3, 2002 Axiom was released under the Modified BSD license, including this document. On August 27, 2003 Axiom was released as free and open source software available for download from the Free Software Foundation's website, Savannah.

Work on Axiom has had the generous support of the Center for Algorithms and Interactive Scientific Computation (CAISS) at City College of New York. Special thanks go to Dr. Gilbert Baumslag for his support of the long term goal.

The online version of this documentation is roughly 1000 pages. In order to make printed versions we've broken it up into three volumes. The first volume is tutorial in nature. The second volume is for programmers. The third volume is reference material. We've also added a fourth volume for developers. All of these changes represent an experiment in print-on-demand delivery of documentation. Time will tell whether the experiment succeeded.

Axiom has been in existence for over thirty years. It is estimated to contain about three hundred man-years of research and has, as of September 3, 2003, 143 people listed in the credits. All of these people have contributed directly or indirectly to making Axiom available. Axiom is being passed to the next generation. I'm looking forward to future milestones.

With that in mind I've introduced the theme of the "30 year horizon". We must invent the tools that support the Computational Mathematician working 30 years from now. How will research be done when every bit of mathematical knowledge is online and instantly available? What happens when we scale Axiom by a factor of 100, giving us 1.1 million domains? How can we integrate theory with code? How will we integrate theorems and proofs of the mathematics with space-time complexity proofs and running code? What visualization tools are needed? How do we support the conceptual structures and semantics of mathematics in effective ways? How do we support results from the sciences? How do we teach the next generation to be effective Computational Mathematicians?

The "30 year horizon" is much nearer than it appears.

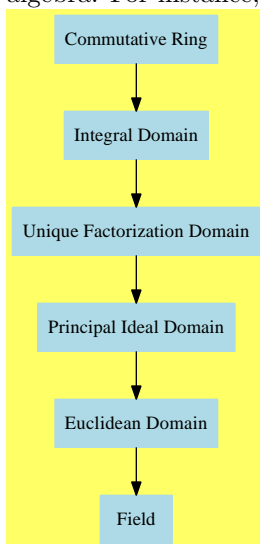

Tim Daly  
CAISS, City College of New York

# Chapter 1

## Categories

Axiom has 3 main algebra components, Categories, Domains, and Packages. If we make an analogy to dressmaking, you can consider the Categories to be hierarchies of properties of things, like patterns, colors, or fabrics. Domains are instances of things based on category choices, such as a dress with a particular style, fabric, color, etc. Packages are tools that work with dresses such as irons, sewing machines, etc.

Axiom is based on abstract algebra and uses it as a scaffolding for constructing well-formed algebra. For instance, in abstract algebra there is a strict subset hierarchy, like:

— `algebrahierarchy.dotpic` —

```

"Integral Domain"
  [color=lightblue,href="bookvol10.2.pdf#nameddest=INTDOM"];
"Unique Factorization Domain"
  [color=lightblue,href="bookvol10.2.pdf#nameddest=UFD"];
"Principal Ideal Domain"
  [color=lightblue,href="bookvol10.2.pdf#nameddest=PID"];
"Euclidean Domain"
  [color=lightblue,href="bookvol10.2.pdf#nameddest=EUCDOM"];
"Field"
  [color=lightblue,href="bookvol10.2.pdf#nameddest=FIELD"];

"Commutative Ring" -> "Integral Domain"
"Integral Domain" -> "Unique Factorization Domain"
"Unique Factorization Domain" -> "Principal Ideal Domain"
"Principal Ideal Domain" -> "Euclidean Domain"
"Euclidean Domain" -> "Field"

}
```

---

## Chapter 2

# Category Layer 1

In general, we use several colors in the graph images. The “lightblue” color indicates a category that is in the direct inheritance path. The “green” (#00EE00) color indicates a category or domain used in the exports. The “seagreen” (a dark green, indicates a category or domain which is used but does not correspond to the signature of an existing category. The system can infer that this “subsumption node” matches the category. A “yellow” color indicates a domain.

### Category (CATEGORY)

---

#### Category Laws:

- Left identity:  $\text{id} . f = f$
- Right identity:  $f . \text{id} = f$
- Associativity:  $f . (g . h) = (f . g) . h$

---

This is the root of the category hierarchy and is not represented by code.

This category exports the attributes in the AXIOM Library.

See Also:

o )show BasicType

See:

⇐ “Category” (CATEGORY) 2 on page 3

**Exports:** Nothing

**Attributes Exported:**

- **finiteAggregate** is true if it is an aggregate with a finite number of elements.
- **commutative**(“\*”) is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation **recip** can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all x.
- **rightUnitary** is true if  $x * 1 = x$  for all x.
- **noZeroDivisors** is true if  $x * y \neq 0$  implies both x and y are non-zero.
- **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is **associates?(a,b)** returns true if and only if **unitCanonical(a) = unitCanonical(b)**.
- **canonicalsClosed** is true if **unitCanonical(a)\*unitCanonical(b) = unitCanonical(a\*b)**.
- **arbitraryPrecision** means the user can set the precision for subsequent calculations.
- **partiallyOrderedSet** is true if a set with  $<$  which is transitive, but  $\text{not}(a < b \text{ or } a = b)$  does not necessarily imply  $b < a$ .

- **central** is true if, given an algebra over a ring  $R$ , the image of  $R$  is the center of the algebra, i.e. the set of members of the algebra which commute with all others is precisely the image of  $R$  in the algebra.
- **noetherian** is true if all of its ideals are finitely generated.
- **additiveValuation** implies  
 $\text{euclideanSize}(a*b) = \text{euclideanSize}(a) + \text{euclideanSize}(b)$ .
- **multiplicativeValuation** implies  
 $\text{euclideanSize}(a*b) = \text{euclideanSize}(a) * \text{euclideanSize}(b)$ .
- **NullSquare** means that  $[x, x] = 0$  holds. See `LieAlgebra`.
- **JacobiIdentity** means that  $[x, [y, z]] + [y, [z, x]] + [z, [x, y]] = 0$  holds. See `LieAlgebra`.
- **canonical** is true if and only if distinct elements have distinct data structures. For example, a domain of mathematical objects which has the **canonical** attribute means that two objects are mathematically equal if and only if their data structures are equal.
- **approximate** means “is an approximation to the real numbers”.
- **complex** means that this domain has  $\sqrt{-1}$

++ \spad{partiallyOrderedSet} is true if
++ a set with \spadop{<} which is transitive,
++ but \spad{not(a < b or a = b)}
++ does not necessarily imply \spad{b<a}.
central
++ \spad{central} is true if, given an algebra over a ring R, the image
++ of R is the center of the algebra, For example, the set of members of
++ the algebra which commute with all others is precisely the image of
++ R in the algebra.
noetherian
++ \spad{noetherian} is true if all of its ideals are finitely generated.
additiveValuation
++ \spad{additiveValuation} implies
++ \spad{euclideanSize(a*b)=euclideanSize(a)+euclideanSize(b)}.
multiplicativeValuation
++ \spad{multiplicativeValuation} implies
++ \spad{euclideanSize(a*b)=euclideanSize(a)*euclideanSize(b)}.
NullSquare
++ \axiom{NullSquare} means that \axiom{[x,x] = 0} holds.
++ See \axiomType{LieAlgebra}.
JacobiIdentity
++ \axiom{JacobiIdentity} means that
++ \axiom{[x,[y,z]]+[y,[z,x]]+[z,[x,y]] = 0} holds.
++ See \axiomType{LieAlgebra}.
canonical
++ \spad{canonical} is true if and only if distinct elements have
++ distinct data structures. For example, a domain of mathematical
++ objects which has the \spad{canonical} attribute means that two
++ objects are mathematically equal if and only if their data
++ structures are equal.
approximate
++ \spad{approximate} means "is an approximation to the real numbers".

```

=====
ModularAlgebraicGcdOperations
=====

```

This category specifies operations needed by ModularAlgebraicGcd package. Since we have multiple implementations we specify interface here and put implementations in separate packages. Most operations are done using special purpose abstract representation. Appropriate types are passed as parameters: MPT is type of modular polynomials in one variable with coefficients in some algebraic extension. MD is type of modulus. Final results are converted to packed representation, with coefficients (from prime field) stored in one array and exponents (in main variable and in auxiliary variables representing generators of algebraic extension) stored in parallel array.

---

**Exports:**

```

canonicalIfCan  degree  MPtoMPT  packExps  packModulus
pseudoRem      repack1  zero?

```

These are directly exported but not implemented:

```

canonicalIfCan : (MPT,MD) -> Union(MPT,"failed")
degree : MPT -> Integer
MPTtoMPT : (Polynomial(Integer),Symbol,List(Symbol),MD) -> MPT
packExps : (Integer,Integer,MD) -> SortedExponentVector
packModulus : (List(Polynomial(Integer)),List(Symbol),Integer) ->
              Union(MD,"failed")
pseudoRem : (MPT,MPT,MD) -> MPT
repack1 : (MPT,U32Vector,Integer,MD) -> Void
zero? : MPT -> Boolean

```

```

)abbrev category MAGCDOC ModularAlgebraicGcdOperations
++ Description: This category specifies operations needed by
++ ModularAlgebraicGcd package. Since we have multiple
++ implementations we specify interface here and put
++ implementations in separate packages. Most operations
++ are done using special purpose abstract representation.
++ Appropriate types are passed as parameters: MPT is type
++ of modular polynomials in one variable with coefficients
++ in some algebraic extension. MD is type of modulus.
++ Final results are converted to packed representation,
++ with coefficients (from prime field) stored in one
++ array and exponents (in main variable and in auxiliary
++ variables representing generators of algebraic extension)
++ stored in parallel array.
ModularAlgebraicGcdOperations(MPT : Type, MD : Type) : Category ==
Exports where
  MP ==> Polynomial Integer
  PA ==> U32Vector
Exports ==> with
  pseudoRem : (MPT, MPT, MD) -> MPT
    ++ pseudoRem(x, y, m) computes pseudoremainder of x by y
    ++ modulo m.
  canonicalIfCan : (MPT, MD) -> Union(MPT, "failed")
    ++ canonicalIfCan(x, m) tries to divide x by its leading
    ++ coefficient modulo m.
  packModulus : (List MP, List(Symbol), Integer) -> Union(MD, "failed")
    ++ packModulus(lp, ls, p) converts lp, ls and prime p which
    ++ together describe algebraic extension to packed
    ++ representation.
  MPTtoMPT : (MP, Symbol, List(Symbol), MD) -> MPT
    ++ MPTtoMPT(p, s, ls, m) converts p to packed representation.
  zero? : MPT -> Boolean
    ++ zero?(x) checks if x is zero.
  degree : MPT -> Integer
    ++ degree(x) gives degree of x.

```

```

packExps : (Integer, Integer, MD) -> SortedExponentVector
++ packExps(d, s, m) produces vector of exponents up
++ to degree d. s is size (degree) of algebraic extension.
++ Use together with repack1.
repack1 : (MPT, PA, Integer, MD) -> Void
++ repack1(x, a, d, m) stores coefficients of x in a.
++ d is degree of x. Corresponding exponents are given
++ by packExps.

++ Date Last Updated: 11 May 1993
++ Description:
++ Category for the other special functions;
```

```
SpecialFunctionCategory(): Category == with
  abs :      $ -> $
      ++ abs(x) returns the absolute value of x.
  Gamma:    $ -> $
```

```

    ++ Gamma(x) is the Euler Gamma function.
Beta:      ($,$)->$
    ++ Beta(x,y) is \spad{Gamma(x) * Gamma(y)/Gamma(x+y)}.
digamma:   $ -> $
    ++ digamma(x) is the logarithmic derivative of \spad{Gamma(x)}
    ++ (often written \spad{psi(x)} in the literature).
polygamma: ($, $) -> $
    ++ polygamma(k,x) is the \spad{k-th} derivative of \spad{digamma(x)},
    ++ (often written \spad{psi(k,x)} in the literature).
Gamma:     ($, $) -> $
    ++ Gamma(a,x) is the incomplete Gamma function.
besselJ:   ($,$) -> $
    ++ besselJ(v,z) is the Bessel function of the first kind.
besselY:   ($,$) -> $
    ++ besselY(v,z) is the Bessel function of the second kind.
besselI:   ($,$) -> $
    ++ besselI(v,z) is the modified Bessel function of the first kind.
besselK:   ($,$) -> $
    ++ besselK(v,z) is the modified Bessel function of the second kind.
airyAi:    $ -> $
    ++ airyAi(x) is the Airy function \spad{Ai(x)}.
airyBi:    $ -> $
    ++ airyBi(x) is the Airy function \spad{Bi(x)}.

Aggregate examples

=====

The notion of aggregate serves to model any data structure aggregate, designating any collection of objects, with heterogenous or homogeneous members, with a finite or infinite number of members, explicitly or implicitly represented. An aggregate can in principle represent everything from a string of characters to abstract sets such as "the set of  $x$  satisfying relation  $r(x)$ "

An attribute "finiteAggregate" is used to assert that a domain has a finite number of elements.

See Also:  
o )show Aggregate

---

See:

⇒ "HomogeneousAggregate" (HOAGG) 4 on page 242  
⇐ "Type" (TYPE) 2 on page 117

**Attributes exported:**

- nil

**Exports:**

empty? eq? less? more? sample size?

**Attributes Used:**

- **finiteAggregate** is true if it is an aggregate with a finite number of elements.

These are implemented by this category:

```
empty? : % -> Boolean
eq? : (%,% ) -> Boolean
less? : (% ,NonNegativeInteger) -> Boolean
more? : (% ,NonNegativeInteger) -> Boolean
sample : () -> %
size? : (% ,NonNegativeInteger) -> Boolean
```

=====
EltableAggregate examples
=====

```

An eltable aggregate is one which can be viewed as a function. For example, the list [1,7,4] can be applied to 0,1, and 2 respectively will return the integers 1, 7, and 4; thus this list may be viewed as mapping 0 to 1, 1 to 7 and 2 to 4. In general, an aggregate can map members of a domain Dom to an image domain Im.

See Also:  
o )show EltableAggregate

---

See:

⇒ “IndexedAggregate” (IXAGG) [5](#) on page [382](#)  
⇐ “Eltable” (ELTAB) [2](#) on page [52](#)

**Exports:**

```
elt  qelt  qsetelt!  setelt  ??
```

### Attributes Used:

- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.

These are part of this category's direct exports:

```
elt : (% , Dom, Im) -> Im
setelt : (% , Dom, Im) -> Im if $ has shallowlyMutable
```

These are implemented by this category:

```
qelt : (% , Dom) -> Im
qsetelt! : (% , Dom, Im) -> Im if $ has shallowlyMutable
```

These exports come from (p52) Eltable():

```
?.? : (% , Dom) -> Im
```

### — category ELTAGG EltableAggregate —

```
)abbrev category ELTAGG EltableAggregate
++ Author: Michael Monagan; revised by Manuel Bronstein and Richard Jenks
++ Date Created: August 87 through August 88
++ Date Last Updated: April 1991
++ Description:
++ An eltable aggregate is one which can be viewed as a function.
++ For example, the list [1,7,4] can applied to 0,1, and 2 respectively
++ will return the integers 1, 7, and 4; thus this list may be viewed as
++ mapping 0 to 1, 1 to 7 and 2 to 4. In general, an aggregate
++ can map members of a domain Dom to an image domain Im.

EltableAggregate(Dom:SetCategory, Im:Type): Category ==
-- This is separated from Eltable
-- and series won't have to support qelt's and setelt's.
Eltable(Dom, Im) with
  elt : (% , Dom, Im) -> Im
    ++ elt(u, x, y) applies u to x if x is in the domain of u,
    ++ and returns y otherwise.
    ++ For example, if u is a polynomial in \axiom{x} over the rationals,
    ++ \axiom{elt(u,n,0)} may define the coefficient of \axiom{x}
    ++ to the power n, returning 0 when n is out of range.
  qelt: (% , Dom) -> Im
    ++ qelt(u, x) applies \axiom{u} to \axiom{x} without checking whether
    ++ \axiom{x} is in the domain of \axiom{u}. If \axiom{x} is not
```

```

++ in the domain of \axiom{u} a memory-access violation may occur.
++ If a check on whether \axiom{x} is in the domain of \axiom{u}
++ is required, use the function \axiom{elt}.
if % has shallowlyMutable then
setelt : (% , Dom, Im) -> Im
  ++ setelt(u,x,y) sets the image of x to be y under u,
  ++ assuming x is in the domain of u.
  ++ Error: if x is not in the domain of u.
  -- this function will soon be renamed as setelt!.
qsetelt_!: (% , Dom, Im) -> Im
  ++ qsetelt!(u,x,y) sets the image of \axiom{x} to be \axiom{y}
  ++ under \axiom{u}, without checking that \axiom{x} is in
  ++ the domain of \axiom{u}.
  ++ If such a check is required use the function \axiom{setelt}.
add
qelt(a, x) == elt(a, x)
if % has shallowlyMutable then
qsetelt_!(a, x, y) == (a.x := y)

)abbrev category FILECAT FileCategory
++ Author: Stephen M. Watt, Victor Miller
++ Date Last Updated: June 4, 1991
++ Description:
++ This category provides an interface to operate on files in the
++ computer's file system. The precise method of naming files
++ is determined by the Name parameter. The type of the contents
++ of the file is determined by S.
```

```
FileCategory(Name, S): Category == FCdefinition where
  Name:      SetCategory
  S:         SetCategory
  IOMode ==> String -- Union("input", "output", "closed")
```

```
FCdefinition == SetCategory with
  open: Name -> %
      ++ open(s) returns the file s open for input.
```

```
open: (Name, IOMode) -> %
```

```

++ open(s,mode) returns a file s open for operation in the
++ indicated mode: "input" or "output".

reopen_!: (% , IOMode) -> %
++ reopen!(f,mode) returns a file f reopened for operation in the
++ indicated mode: "input" or "output".
++ \spad{reopen!(f,"input")} will reopen the file f for input.

close_!: % -> %
++ close!(f) returns the file f closed to input and output.

name: % -> Name
++ name(f) returns the external name of the file f.

iomode: % -> IOMode
++ iomode(f) returns the status of the file f. The input/output
++ status of f may be "input", "output" or "closed" mode.

read_!: % -> S
++ read!(f) extracts a value from file f. The state of f is
++ modified so a subsequent call to \spadfun{read!} will return
++ the next element.

write_!: (% ,S) -> S
++ write!(f,s) puts the value s into the file f.
++ The state of f is modified so subsequents call to \spad{write!}
++ will append one after another.

flush: % -> Void
++ flush(f) makes sure that buffered data is written out

)abbrev category FINITE Finite
++ Description:
++ The category of domains composed of a finite set of elements.
++ We include the functions \spadfun{lookup} and \spadfun{index}
++ to give a bijection between the finite set and an initial
++ segment of positive integers.
++
++ Axioms:\br
++ \tab{5}\spad{lookup(index(n)) = n}\br
++ \tab{5}\spad{index(lookup(s)) = s}

Finite(): Category == SetCategory with

size: () -> NonNegativeInteger
++ size() returns the number of elements in the set.

index: PositiveInteger -> %
++ index(i) takes a positive integer i less than or equal
++ to \spad{size()} and
++ returns the \spad{i}-th element of the set.
++ This operation establishes a bijection
++ between the elements of the finite set and \spad{1..size()}.

lookup: % -> PositiveInteger
++ lookup(x) returns a positive integer such that
++ \spad{x = index lookup x}.

random: () -> %
++ random() returns a random element from the set.

enumerate: () -> List %
++ enumerate() returns a list of elements of the set
++
++X enumerate()$OrderedVariableList([p,q])

```

```

add

random() == index((1+random(size())$%))::PositiveInteger)

enumerate() == [index(i::PositiveInteger) for i in 1..size()]

)abbrev category FNCAT FileNameCategory
++ Author: Stephen M. Watt
++ Date Created: 1985
++ Date Last Updated: June 20, 1991
++ Description:
++ This category provides an interface to names in the file system.

FileNameCategory(): Category == SetCategory with
  coerce: String -> %
    ++ coerce(s) converts a string to a file name
    ++ according to operating system-dependent conventions.
  coerce: % -> String
    ++ coerce(fn) produces a string for a file name
    ++ according to operating system-dependent conventions.
  filename: (String, String, String) -> %
    ++ filename(d,n,e) creates a file name with
    ++ d as its directory, n as its name and e as its extension.
    ++ This is a portable way to create file names.
    ++ When d or t is the empty string, a default is used.
  directory: % -> String
    ++ directory(f) returns the directory part of the file name.
  name: % -> String
    ++ name(f) returns the name part of the file name.
  extension: % -> String
    ++ extension(f) returns the type part of the file name.
  exists?: % -> Boolean
    ++ exists?(f) tests if the file exists in the file system.
  readable?: % -> Boolean
    ++ readable?(f) tests if the named file exist and can it be opened

```

```

++ for reading.
writable?: % -> Boolean
++ writable?(f) tests if the named file be opened for writing.
++ The named file need not already exist.
new: (String, String, String) -> %
++ new(d,pref,e) constructs the name of a new writable file with
++ d as its directory, pref as a prefix of its name and
++ e as its extension.
++ When d or t is the empty string, a default is used.
++ An error occurs if a new file cannot be written in the given
++ directory.

=====  
GradedModule examples  
=====

GradedModule(R,E) denotes "E-graded R-module", i.e. collection of R-modules indexed by an abelian monoid E. An element  $g$  of  $G[s]$  for some specific  $s$  in  $E$  is said to be an element of  $G$  with degree  $s$ . Sums are defined in each module  $G[s]$  so two elements of  $G$  have a sum if they have the same degree.

Morphisms can be defined and composed by degree to give the mathematical category of graded modules.

See Also:

=====
HomogeneousAggregate examples
=====

```

A homogeneous aggregate is an aggregate of elements all of the same type.

In the current system, all aggregates are homogeneous. Two attributes characterize classes of aggregates. Aggregates from domains with attribute "finiteAggregate" have a finite number of members. Those with attribute "shallowlyMutable" allow an element to be modified or updated without changing its overall value.

See Also:

o )show HomogeneousAggregate

---

See:

⇒ "BagAggregate" (BGAGG) 5 on page 341  
 ⇒ "Collection" (CLAGG) 5 on page 351

 ⇐ "Aggregate" (AGG) 3 on page 123  
 ⇐ "Evaluable" (EVALAB) 3 on page 137  
 ⇐ "SetCategory" (SETCAT) 3 on page 170

**Attributes exported:**

- nil

**Exports:**

any?	coerce	copy	count	empty
empty?	eq?	eval	every?	hash
latex	less?	map	map!	members
member?	more?	parts	sample	size?
#?	?=?	?~=?		

**Attributes Used:**

- **finiteAggregate** is true if it is an aggregate with a finite number of elements.
- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.

These are directly exported but not implemented:

```

map : ((S -> S),%) -> %
map! : ((S -> S),%) -> % if $ has shallowlyMutable
parts : % -> List S if $ has finiteAggregate

```

These are implemented by this category:

```

any? : ((S -> Boolean),%) -> Boolean
      if $ has finiteAggregate
coerce : % -> OutputForm if S has SETCAT
count : (S,%) -> NonNegativeInteger
      if S has SETCAT and $ has finiteAggregate
count : ((S -> Boolean),%) -> NonNegativeInteger
      if $ has finiteAggregate
eval : (%,List Equation S) -> %
      if S has EVALAB S and S has SETCAT
every? : ((S -> Boolean),%) -> Boolean if $ has finiteAggregate
members : % -> List S if $ has finiteAggregate
member? : (S,%) -> Boolean
      if S has SETCAT and $ has finiteAggregate
#? : % -> NonNegativeInteger if $ has finiteAggregate
?? : (%,% ) -> Boolean if S has SETCAT

```

These exports come from (p123) Aggregate:

```

copy : % -> %
empty : () -> %
empty? : % -> Boolean
eq? : (%,% ) -> Boolean
less? : (% , NonNegativeInteger) -> Boolean
more? : (% , NonNegativeInteger) -> Boolean
sample : () -> %
size? : (% , NonNegativeInteger) -> Boolean

```

These exports come from (p137) Evaluable(a:Type):

```

eval : (% , List S , List S) -> %
      if S has EVALAB S and S has SETCAT
eval : (% , S , S) -> %
      if S has EVALAB S and S has SETCAT
eval : (% , Equation S) -> %
      if S has EVALAB S and S has SETCAT

```

These exports come from (p170) SetCategory():

```

hash : % -> SingleInteger if S has SETCAT
?~=? : (%,% ) -> Boolean if S has SETCAT
latex : % -> String if S has SETCAT

```

```

++ Date Created: February 1995
++ Date Last Updated: June 1995
++ Description:
++ \axiomType{PartialDifferentialEquationsSolverCategory} is the
++ \axiom{category} for describing the set of PDE solver \axiom{domains}
++ with \axiomFun{measure} and \axiomFun{PDESolve}.

-- PDEA      ==> Record(xmin:F,xmax:F,ymin:F,ymax:F,ngx:NNI,ngy:NNI,
--                  pde:List Expression Float, bounds:List List Expression Float,
--                  st:String, tol:DF)

-- measure:(RoutinesTable,PDEA) -> Record(measure:F,explanations:String)
--   ++ measure(R,args) calculates an estimate of the ability of a particular
--   ++ method to solve a problem.
--   ++
--   ++ This method may be either a specific NAG routine or a strategy (such
--   ++ as transforming the function from one which is difficult to one which

```

```

-- ++ is easier to solve).
-- ++
-- ++ It will call whichever agents are needed to perform analysis on the
-- ++ problem in order to calculate the measure. There is a parameter,
-- ++ labelled \axiom{sofar}, which would contain the best compatibility
-- ++ found so far.

-- PDESolve: PDEA -> Result
-- ++ PDESolve(args) performs the integration of the
-- ++ function given the strategy or method returned by \axiomFun{measure}.

— category SEGXCAT SegmentExpansionCategory —

```

)abbrev category SEGXCAT SegmentExpansionCategory
++ Author: Stephen M. Watt
++ Date Created: June 5, 1991
++ Description:
++ This category provides an interface for expanding segments to
++ a stream of elements.

SegmentExpansionCategory(S: OrderedRing, L: StreamAggregate(S)): Category ==
  SegmentCategory(S) with
    expand: List % -> L
      ++ expand(l) creates a new value of type L in which each segment
      ++ \spad{l..h by k} is replaced with \spad{1, 1+k, ... 1N},
      ++ where \spad{1N <= h < 1N+k}.
      ++ For example, \spad{expand [1..4, 7..9]} = [1,2,3,4,7,8,9]}.
    expand: % -> L
      ++ expand(l..h by k) creates value of type L with elements
      ++ \spad{1, 1+k, ... 1N} where \spad{1N <= h < 1N+k}.
      ++ For example, \spad{expand(1..5 by 2)} = [1,3,5]}.
    map: (S -> S, %) -> L
      ++ map(f,l..h by k) produces a value of type L by applying f
      ++ to each of the successive elements of the segment, that is,
      ++ \spad{[f(1), f(1+k), ..., f(1N)]}, where \spad{1N <= h < 1N+k}.

=====
StepThrough examples
=====

```

A class of objects which can be 'stepped through'.

Repeated applications of nextItem is guaranteed never to return duplicate items and only return "failed" after exhausting all elements of the domain. This assumes that the sequence starts with init(). For infinite domains, repeated application of nextItem is not required to reach all possible domain elements starting from any initial element.

Conditional attributes:

infinite -- repeated nextItem's are never "failed".

Exports ==> Category
Implementation ==>
SetCategory with

create3Space : () -> %
++ create3Space() creates a \spadtype{ThreeSpace} object capable of
++ holding point, curve, mesh components and any combination.

create3Space : SUBSPACE -> %
++ create3Space(s) creates a \spadtype{ThreeSpace} object containing
++ objects pre-defined within some \spadtype{SubSpace} s.

numberOfComponents : % -> NNI
++ numberOfComponents(s) returns the number of distinct
++ object components in the indicated \spadtype{ThreeSpace}, s, such
++ as points, curves, polygons, and constructs.

numberOfComposites : % -> NNI
++ numberOfComposites(s) returns the number of supercomponents,
++ or composites, in the \spadtype{ThreeSpace}, s; Composites are
++ arbitrary groupings of otherwise distinct and unrelated components;
++ A \spadtype{ThreeSpace} need not have any composites defined at all
++ and, outside of the requirement that no component can belong
++ to more than one composite at a time, the definition and
++ interpretation of composites are unrestricted.

merge : L % -> %
++ merge([s1,s2,...,sn]) will create a new \spadtype{ThreeSpace} that
++ has the components of all the ones in the list; Groupings of
++ components into composites are maintained.

```

```

merge : (%,% ) -> %
++ merge(s1,s2) will create a new \spadtype{ThreeSpace} that has the
++ components of \spad{s1} and \spad{s2}; Groupings of components
++ into composites are maintained.

composite : L % -> %
++ composite([s1,s2,...,sn]) will create a new \spadtype{ThreeSpace}
++ that is a union of all the components from each
++ \spadtype{ThreeSpace} in the parameter list, grouped as a composite.

components : % -> L %
++ components(s) takes the \spadtype{ThreeSpace} s, and creates a list
++ containing a unique \spadtype{ThreeSpace} for each single component
++ of s. If s has no components defined, the list returned is empty.

composites : % -> L %
++ composites(s) takes the \spadtype{ThreeSpace} s, and creates a list
++ containing a unique \spadtype{ThreeSpace} for each single composite
++ of s. If s has no composites defined (composites need to be
++ explicitly created), the list returned is empty. Note that not all
++ the components need to be part of a composite.

copy : % -> %
++ copy(s) returns a new \spadtype{ThreeSpace} that is an exact copy
++ of s.

enterPointData : (% ,L POINT) -> NNI
++ enterPointData(s,[p0,p1,...,pn]) adds a list of points from p0
++ through pn to the \spadtype{ThreeSpace}, s, and returns the index,
++ to the starting point of the list;

modifyPointData : (% ,NNI,POINT) -> %
++ modifyPointData(s,i,p) changes the point at the indexed
++ location i in the \spadtype{ThreeSpace}, s, to that of point p.
++ This is useful for making changes to a point which has been
++ transformed.

-- 3D primitives

point : (% ,POINT) -> %
++ point(s,p) adds a point component defined by the point, p,
++ specified as a list from \spad{List(R)}, to the
++ \spadtype{ThreeSpace}, s, where R is the \spadtype{Ring} over
++ which the point is defined.

point : (% ,L R) -> %
++ point(s,[x,y,z]) adds a point component defined by a list of
++ elements which are from the \spad{PointDomain(R)} to the
++ \spadtype{ThreeSpace}, s, where R is the \spadtype{Ring} over
++ which the point elements are defined.

```

```

point      : (% , NNI) -> %
++ point(s,i) adds a point component which is placed into a component
++ list of the \spadtype{ThreeSpace}, s, at the index given by i.

point      : POINT -> %
++ point(p) returns a \spadtype{ThreeSpace} object which is composed
++ of one component, the point p.

point      : % -> POINT
++ point(s) checks to see if the \spadtype{ThreeSpace}, s, is
++ composed of only a single point and if so, returns the point.
++ An error is signaled otherwise.

point?     : % -> B
++ point?(s) queries whether the \spadtype{ThreeSpace}, s, is
++ composed of a single component which is a point and returns the
++ boolean result.

curve      : (% , L POINT) -> %
++ curve(s, [p0,p1,...,pn]) adds a space curve component defined by a
++ list of points \spad{p0} through \spad{pn}, to the
++ \spadtype{ThreeSpace} s.

curve      : (% , L L R) -> %
++ curve(s, [[p0],[p1],..., [pn]]) adds a space curve which is a list of
++ points p0 through pn defined by lists of elements from the domain
++ \spad{PointDomain(m,R)}, where R is the \spadtype{Ring} over which
++ the point elements are defined and m is the dimension of the
++ points, to the \spadtype{ThreeSpace} s.

curve      : L POINT -> %
++ curve([p0,p1,p2,...,pn]) creates a space curve defined
++ by the list of points \spad{p0} through \spad{pn}, and returns the
++ \spadtype{ThreeSpace} whose component is the curve.

curve      : % -> L POINT
++ curve(s) checks to see if the \spadtype{ThreeSpace}, s, is
++ composed of a single curve defined by a list of points and if so,
++ returns the curve, that is, list of points. An error is signaled
++ otherwise.

curve?     : % -> B
++ curve?(s) queries whether the \spadtype{ThreeSpace}, s, is a curve,
++ that is, has one component, a list of list of points, and returns
++ true if it is, or false otherwise.

closedCurve : (% , L POINT) -> %
++ closedCurve(s, [p0,p1,...,pn,p0]) adds a closed curve component
++ which is a list of points defined by the first element p0 through

```

```

++ the last element pn and back to the first element p0 again, to the
++ \spadtype{ThreeSpace} s.

closedCurve : (% ,L L R) -> %
++ closedCurve(s,[[lr0],[lr1],...,[lrn],[lr0]]) adds a closed curve
++ component defined by a list of points \spad{lr0} through
++ \spad{lrn}, which are lists of elements from the domain
++ \spad{PointDomain(m,R)}, where R is the \spadtype{Ring} over which
++ the point elements are defined and m is the dimension of the
++ points, in which the last element of the list of points contains
++ a copy of the first element list, lr0.
++ The closed curve is added to the \spadtype{ThreeSpace}, s.

closedCurve      : L POINT -> %
++ closedCurve(lp) sets a list of points defined by the first element
++ of lp through the last element of lp and back to the first element
++ again and returns a \spadtype{ThreeSpace} whose component is the
++ closed curve defined by lp.

closedCurve      : % -> L POINT
++ closedCurve(s) checks to see if the \spadtype{ThreeSpace}, s, is
++ composed of a single closed curve component defined by a list of
++ points in which the first point is also the last point, all of
++ which are from the domain \spad{PointDomain(m,R)} and if so,
++ returns the list of points. An error is signaled otherwise.

closedCurve?     : % -> B
++ closedCurve?(s) returns true if the \spadtype{ThreeSpace} s
++ contains a single closed curve component, that is, the first element
++ of the curve is also the last element, or false otherwise.

polygon          : (% ,L POINT) -> %
++ polygon(s,[p0,p1,...,pn]) adds a polygon component defined by a
++ list of points, p0 through pn, to the \spadtype{ThreeSpace} s.

polygon          : (% ,L L R) -> %
++ polygon(s,[[r0],[r1],...,[rn]]) adds a polygon component defined
++ by a list of points \spad{r0} through \spad{rn}, which are lists of
++ elements from the domain \spad{PointDomain(m,R)} to the
++ \spadtype{ThreeSpace} s, where m is the dimension of the points
++ and R is the \spadtype{Ring} over which the points are defined.

polygon          : L POINT -> %
++ polygon([p0,p1,...,pn]) creates a polygon defined by a list of
++ points, p0 through pn, and returns a \spadtype{ThreeSpace} whose
++ component is the polygon.

polygon          : % -> L POINT
++ polygon(s) checks to see if the \spadtype{ThreeSpace}, s, is
++ composed of a single polygon component defined by a list of

```

```

++ points, and if so, returns the list of points; An error is
++ signaled otherwise.

polygon?      : % -> B
++ polygon?(s) returns true if the \spadtype{ThreeSpace} s contains
++ a single polygon component, or false otherwise.

mesh         : (% ,L L POINT,L PROP,PROP) -> %
++ mesh(s,[[p0],[p1],...,[pn]],[props],prop) adds a surface component,
++ defined over a list curves which contains lists of points, to the
++ \spadtype{ThreeSpace} s; props is a list which contains the
++ subspace component properties for each surface parameter, and
++ prop is the subspace component property by which the points are
++ defined.

mesh         : (% ,L L L R,L PROP,PROP) -> %
++ mesh(s, LLLR, [props], prop)
++ where LLLR is of the form:
++ [[r10]...,[r1m]],[[r20]...,[r2m]],...,[rn0]...,[rnm]],
++ adds a surface component to the \spadtype{ThreeSpace} s, which is
++ defined over a rectangular domain of size WxH where W is the number
++ of lists of points from the domain \spad{PointDomain(R)} and H is
++ the number of elements in each of those lists; lprops is the list
++ of the subspace component properties for each curve list, and
++ prop is the subspace component property by which the points are
++ defined.

mesh         : (% ,L L POINT,B,B) -> %
++ mesh(s, LLP, close1, close2)
++ where LLP is of the form [[p0],[p1],...,[pn]] adds a surface
++ component to the \spadtype{ThreeSpace}, which is defined over a
++ list of curves, in which each of these curves is a list of points.
++ The boolean arguments close1 and close2 indicate how the surface
++ is to be closed. Argument close1 equal true
++ means that each individual list (a curve) is to be closed, that is,
++ the last point of the list is to be connected to the first point.
++ Argument close2 equal true
++ means that the boundary at one end of the surface is to be
++ connected to the boundary at the other end, that is, the boundaries
++ are defined as the first list of points (curve) and
++ the last list of points (curve).

mesh         : (% ,L L L R,B,B) -> %
++ mesh(s, LLLR, close1, close2)
++ where LLLR is of the form
++ [[r10]...,[r1m]],[[r20]...,[r2m]],...,[rn0]...,[rnm]],
++ adds a surface component to the \spadtype{ThreeSpace} s, which is
++ defined over a rectangular domain of size WxH where W is the number
++ of lists of points from the domain \spad{PointDomain(R)} and H is
++ the number of elements in each of those lists; the booleans close1

```

```

++ and close2 indicate how the surface is to be closed: if close1 is
++ true this means that each individual list (a curve) is to be
++ closed (that is,
++ the last point of the list is to be connected to the first point);
++ if close2 is true, this means that the boundary at one end of the
++ surface is to be connected to the boundary at the other end
++ (the boundaries are defined as the first list of points (curve)
++ and the last list of points (curve)).

mesh      : L L POINT -> %
++ mesh([[p0],[p1],...,[pn]]) creates a surface defined by a list of
++ curves which are lists, p0 through pn, of points, and returns a
++ \spadtype{ThreeSpace} whose component is the surface.

mesh      : (L L POINT,B,B) -> %
++ mesh([[p0],[p1],...,[pn]], close1, close2) creates a surface
++ defined over a list of curves, p0 through pn, which are lists of
++ points; the booleans close1 and close2 indicate how the surface is
++ to be closed: close1 set to true means that each individual list
++ (a curve) is to be closed (that is, the last point of the list is
++ to be connected to the first point); close2 set to true means
++ that the boundary at one end of the surface is to be connected to
++ the boundary at the other end (the boundaries are defined as the
++ first list of points (curve) and the last list of points (curve));
++ the \spadtype{ThreeSpace} containing this surface is returned.

mesh      : % -> L L POINT
++ mesh(s) checks to see if the \spadtype{ThreeSpace}, s, is
++ composed of a single surface component defined by a list curves
++ which contain lists of points, and if so, returns the list of
++ lists of points; An error is signaled otherwise.

mesh?     : % -> B
++ mesh?(s) returns true if the \spadtype{ThreeSpace} s is composed
++ of one component, a mesh comprising a list of curves which are lists
++ of points, or returns false if otherwise

lp        : % -> L POINT
++ lp(s) returns the list of points component which the
++ \spadtype{ThreeSpace}, s, contains; these points are used by
++ reference, that is, the component holds indices referring to the
++ points rather than the points themselves. This allows for sharing
++ of the points.

l1lip     : % -> L L L NNI
++ l1lip(s) checks to see if the \spadtype{ThreeSpace}, s, is
++ composed of a list of components, which are lists of curves,
++ which are lists of indices to points, and if so, returns the list
++ of lists of lists; An error is signaled otherwise.

```

```

lllp          : % -> L L L POINT  -- used by view3D
++ lllp(s) checks to see if the \spadtype{ThreeSpace}, s, is
++ composed of a list of components, which are lists of curves,
++ which are lists of points, and if so, returns the list of
++ lists of lists; An error is signaled otherwise.

llprop        : % -> L L PROP      -- used by view3D
++ llprop(s) checks to see if the \spadtype{ThreeSpace}, s, is
++ composed of a list of curves which are lists of the
++ subspace component properties of the curves, and if so, returns the
++ list of lists; An error is signaled otherwise.

lprop         : % -> L PROP        -- used by view3D
++ lprop(s) checks to see if the \spadtype{ThreeSpace}, s, is
++ composed of a list of subspace component properties, and if so,
++ returns the list; An error is signaled otherwise.

objects       : % -> OBJ3D
++ objects(s) returns the \spadtype{ThreeSpace}, s, in the form of a
++ 3D object record containing information on the number of points,
++ curves, polygons and constructs comprising the
++ \spadtype{ThreeSpace}..

check         : % -> %             -- used by mesh
++ check(s) returns lllpt, list of lists of lists of point information
++ about the \spadtype{ThreeSpace} s.

subspace      : % -> SUBSPACE
++ subspace(s) returns the \spadtype{SubSpace} which holds all the
++ point information in the \spadtype{ThreeSpace}, s.

coerce        : % -> 0
++ coerce(s) returns the \spadtype{ThreeSpace} s to Output format.

)abbrev category AFSPCAT AffineSpaceCategory
++ Author: Gaetan Hache
++ Date Created: 17 nov 1992
++ Date Last Updated: May 2010 by Tim Daly
++ Description:
++ The following is all the categories and domains related to projective
++ space and part of the PAFF package
AffineSpaceCategory(K:Field):Category == Implementation where

LIST ==> List
INT ==> Integer
NNI ==> NonNegativeInteger

Implementation ==>
SetCategoryWithDegree with

origin: () -> %

affinePoint: LIST(K) -> %
++ affinePoint creates a affine point from a list

```

```

definingField: % -> K

coerce: % -> List(K)

coerce: LIST(K) -> %
  ++ coerce a list of K to a affine point.

orbit: % -> LIST %
  ++ orbit(p) returns the orbit of the point p according to the
  ++ characteristic of K, that is, for q= char K,
  ++ orbit(p) = \{ p, p**q, p**(q**2), p**(q**3), ..... \}

orbit: (% ,NNI) -> LIST %
  ++ orbit(p,n) returns the orbit of the point p according to n, that is
  ++ orbit(p,n) = \{ p, p**n, p**(n**2), p**(n**3), ..... \}

conjugate: (% ,NNI) -> %
  ++ conjugate(p,n) returns p**n, that is all the coordinates of p
  ++ to the power of n

conjugate: % -> %
  ++ conjugate(p) returns conjugate(p,n) where n is the characteristic
  ++ of the ground field.

removeConjugate: (LIST(%),NNI) -> LIST(%)
  ++ removeConjugate(lp,n) returns a list of points such that no points
  ++ in the list is the conjugate (according to n) of another point.

removeConjugate: LIST(%) -> LIST(%)
  ++ removeConjugate(lp) returns removeConjugate(lp,n)
  ++ where n is the characteristic of the ground field.

rational?: (% ,NNI) -> Boolean
  ++ rational?(p,n) test if the point is rational according to n.

rational?: % -> Boolean
  ++ rational?(p) test if the point is rational according to the
  ++ characteristic of the ground field.

list : % -> LIST(K)
  ++ list returns the list of the coordinates

elt: (% ,INT) -> K
  ++ elt returns the value of a specified coordinates

setelt: (% ,INT,K) -> K
  ++ setelt sets the value of a specified coordinates

pointValue: % -> LIST(K)

```

++ pointValue returns the coordinates of the point or of the point  
 ++ of origin that represent an infinitely close point

```
=====
BagAggregate examples
=====
```

A bag aggregate is an aggregate for which one can insert and extract objects, and where the order in which objects are inserted determines the order of extraction. Examples of bags are stacks, queues, and dequeues.

See Also:

o )show BagAggregate

---

**See:**

⇒ “DictionaryOperations” (DIOPS) 6 on page 449  
 ⇒ “PriorityQueueAggregate” (PRQAGG) 6 on page 543  
 ⇒ “QueueAggregate” (QUAGG) 6 on page 549  
 ⇒ “StackAggregate” (SKAGG) 6 on page 563  
 ⇐ “HomogeneousAggregate” (HOAGG) 4 on page 242

**Exports:**

any?	bag	coerce	copy	count
empty	empty?	eq?	eval	every?
extract!	hash	insert!	inspect	latex
less?	map	map!	member?	members
more?	parts	sample	size?	#?
?=?	?~=?			

**Attributes Exported:**

- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.
- **nil**

These are directly exported but not implemented:

```
extract! : % -> S
insert!  : (S,% ) -> %
inspect  : % -> S
```

These are implemented by this category:

```
bag : List S -> %
```

These exports come from (p242) HomogeneousAggregate(S:Type):

```
any? : ((S -> Boolean),%) -> Boolean
      if $ has finiteAggregate
coerce : % -> OutputForm if S has SETCAT
copy : % -> %
count : (S,%) -> NonNegativeInteger
      if S has SETCAT and $ has finiteAggregate
count : ((S -> Boolean),%) -> NonNegativeInteger
      if $ has finiteAggregate
empty : () -> %
empty? : % -> Boolean
eq? : (%,%) -> Boolean
eval : (%,List S,List S) -> %
      if S has EVALAB S and S has SETCAT
eval : (%,S,S) -> %
      if S has EVALAB S and S has SETCAT
eval : (%,Equation S) -> %
      if S has EVALAB S and S has SETCAT
eval : (%,List Equation S) -> %
      if S has EVALAB S and S has SETCAT
every? : ((S -> Boolean),%) -> Boolean if $ has finiteAggregate
hash : % -> SingleInteger if S has SETCAT
latex : % -> String if S has SETCAT
less? : (%,NonNegativeInteger) -> Boolean
map : ((S -> S),%) -> %
map! : ((S -> S),%) -> % if $ has shallowlyMutable
members : % -> List S if $ has finiteAggregate
member? : (S,%) -> Boolean
      if S has SETCAT and $ has finiteAggregate
more? : (%,NonNegativeInteger) -> Boolean
parts : % -> List S if $ has finiteAggregate
sample : () -> %
size? : (%,NonNegativeInteger) -> Boolean
\#? : % -> NonNegativeInteger if $ has finiteAggregate
?? : (%,%) -> Boolean if S has SETCAT
?~? : (%,%) -> Boolean if S has SETCAT
```

=====
Collection examples
=====

```

A collection is a homogeneous aggregate which can be built from a list of members. The operation used to build the aggregate is generically named `construct`. However, each collection provides its own special function with the same name as the data type, except with an initial lower case letter, e.g. `list` for `List`, `flexibleArray` for `FlexibleArray`, and so on.

## — category CLAGG Collection —

```

)abbrev category CLAGG Collection
++ Author: Michael Monagan; revised by Manuel Bronstein and Richard Jenks
++ Date Created: August 87 through August 88
++ Date Last Updated: April 1991
++ Description:
++ A collection is a homogeneous aggregate which can built from
++ list of members. The operation used to build the aggregate is
++ generically named construct. However, each collection
++ provides its own special function with the same name as the
++ data type, except with an initial lower case letter, For example,
++ list for List, flexibleArray for FlexibleArray, and so on.

Collection(S:Type): Category == HomogeneousAggregate(S) with
  construct: List S -> %
    ++ \axiom{construct(x,y,...,z)} returns the collection of elements
    ++ \axiom{x,y,...,z} ordered as given. Equivalently written as
    ++ \axiom{[x,y,...,z]$D}, where
    ++ D is the domain. D may be omitted for those of type List.
  find: (S->Boolean, %) -> Union(S, "failed")
    ++ \axiom{find(p,u)} returns the first x in u such that
    ++ \axiom{p(x)} is true, and "failed" otherwise.
  if % has finiteAggregate then
    reduce: ((S,S)->S,%) -> S
      ++reduce(f,u) reduces the binary operation f across u.
      ++For example, if u is \axiom{[x,y,...,z]} then \axiom{reduce(f,u)}
      ++returns \axiom{f(.f(f(x,y),...),z)}.
      ++Note that if u has one element x, \axiom{reduce(f,u)} returns x.
      ++Error: if u is empty.
      ++
      ++C )clear all
      ++X reduce(+,[C[i]*x**i for i in 1..5])

    reduce: ((S,S)->S,%,S) -> S
      ++ reduce(f,u,x) reduces the binary operation f across u, where x is
      ++ the identity operation of f.
      ++ Same as \axiom{reduce(f,u)} if u has 2 or more elements.
      ++ Returns \axiom{f(x,y)} if u has one element y,
      ++ x if u is empty.
      ++ For example, \axiom{reduce(+,u,0)} returns the
      ++ sum of the elements of u.
    remove: (S->Boolean,%) -> %
      ++ remove(p,u) returns a copy of u removing all elements x such that
      ++ \axiom{p(x)} is true.
      ++ Note that \axiom{remove(p,u)} == [x for x in u | not p(x)].
    select: (S->Boolean,%) -> %
      ++ select(p,u) returns a copy of u containing only those elements
      ++ such \axiom{p(x)} is true.

```

```

++ Note that \axiom{select(p,u) == [x for x in u | p(x)]}.
if S has SetCategory then
  reduce: ((S,S)->S,%,S,S) -> S
    ++ reduce(f,u,x,z) reduces the binary operation f across u,
    ++ stopping when an "absorbing element" z is encountered.
    ++ As for \axiom{reduce(f,u,x)}, x is the identity operation of f.
    ++ Same as \axiom{reduce(f,u,x)} when u contains no element z.
    ++ Thus the third argument x is returned when u is empty.
  remove: (S,%) -> %
    ++ remove(x,u) returns a copy of u with all
    ++ elements \axiom{y = x} removed.
    ++ Note that \axiom{remove(y,c) == [x for x in c | x ^= y]}.
  removeDuplicates: % -> %
    ++ removeDuplicates(u) returns a copy of u with all duplicates
    ++ removed.

if S has ConvertibleTo InputForm then ConvertibleTo InputForm
add
if % has finiteAggregate then

=====
DifferentialVariableCategory examples
=====

```

DifferentialVariableCategory constructs the set of derivatives of a given set of (ordinary) differential indeterminates. If  $x, \dots, y$  is an ordered set of differential indeterminates, and the prime notation is used for differentiation, then the set of derivatives (including zero-th order) of the differential indeterminates is

$x, x', x'', \dots, y, y', y'', \dots$

(Note that in the interpreter, the  $n$ -th derivative of  $y$  is displayed as  $y$  with a subscript  $n$ .) This set is viewed as a set of algebraic indeterminates, totally ordered in a way compatible with differentiation and the given order on the differential indeterminates. Such a total order is called a ranking of the differential indeterminates.

A domain in this category is needed to construct a differential

polynomial domain. Differential polynomials are ordered by a ranking on the derivatives, and by an order (extending the ranking) on the set of differential monomials. One may thus associate a domain in this category with a ranking of the differential indeterminates, just as one associates a domain in the category `OrderedAbelianMonoidSup` with an ordering of the set of monomials in a set of algebraic indeterminates. The ranking is specified through the binary relation `<`. For example, one may define one derivative to be less than another by lexicographically comparing first the order, then the given order of the differential indeterminates appearing in the derivatives. This is the default implementation.

The notion of weight generalizes that of degree. A polynomial domain may be made into a graded ring if a weight function is given on the set of indeterminates. Very often, a grading is the first step in ordering the set of monomials. For differential polynomial domains, this constructor provides a function `\spadfun{weight}`, which allows the assignment of a non-negative number to each derivative of a differential indeterminate. For example, one may define the weight of a derivative to be simply its order (this is the default assignment). This weight function can then be extended to the set of all differential polynomials, providing a graded ring structure.

++ References:Ritt, J.F. "Differential Algebra" (Dover, 1950).
++ Description:
++ \spadtype{DifferentialVariableCategory} constructs the
++ set of derivatives of a given set of
++ (ordinary) differential indeterminates.
++ If x,...,y is an ordered set of differential indeterminates,
++ and the prime notation is used for differentiation, then
++ the set of derivatives (including
++ zero-th order) of the differential indeterminates is
++ x, \spad{x'}, \spad{x''}, ..., y, \spad{y'}, \spad{y''}, ...
++ (Note that in the interpreter, the n-th derivative of y is displayed as
++ y with a subscript n.) This set is
++ viewed as a set of algebraic indeterminates, totally ordered in a
++ way compatible with differentiation and the given order on the
++ differential indeterminates. Such a total order is called a
++ ranking of the differential indeterminates.
++
++ A domain in this category is needed to construct a differential

```

```

++ polynomial domain. Differential polynomials are ordered
++ by a ranking on the derivatives, and by an order (extending the
++ ranking) on
++ on the set of differential monomials. One may thus associate
++ a domain in this category with a ranking of the differential
++ indeterminates, just as one associates a domain in the category
++ \spadtype{OrderedAbelianMonoidSup} with an ordering of the set of
++ monomials in a set of algebraic indeterminates. The ranking
++ is specified through the binary relation \spadfun{<}.
++ For example, one may define
++ one derivative to be less than another by lexicographically comparing
++ first the \spadfun{order}, then the given order of the differential
++ indeterminates appearing in the derivatives. This is the default
++ implementation.
++
++ The notion of weight generalizes that of degree. A
++ polynomial domain may be made into a graded ring
++ if a weight function is given on the set of indeterminates,
++ Very often, a grading is the first step in ordering the set of
++ monomials. For differential polynomial domains, this
++ constructor provides a function \spadfun{weight}, which
++ allows the assignment of a non-negative number to each derivative of a
++ differential indeterminate. For example, one may define
++ the weight of a derivative to be simply its \spadfun{order}
++ (this is the default assignment).
++ This weight function can then be extended to the set of
++ all differential polynomials, providing a graded ring structure.

  ++ elt(op,x) or op(x) applies the unary operator op to x.
  elt      : (OP, %, %) -> %
  ++ elt(op,x,y) or op(x, y) applies the binary operator op to x and y.
  elt      : (OP, %, %, %) -> %
  ++ elt(op,x,y,z) or op(x, y, z) applies the ternary operator op
  ++ to x, y and z.
  elt      : (OP, %, %, %, %) -> %
  ++ elt(op,x,y,z,t) or op(x, y, z, t) applies the 4-ary operator op
  ++ to x, y, z and t.
  elt      : (OP, List %) -> %
  ++ elt(op,[x1,...,xn]) or op([x1,...,xn]) applies the n-ary operator
  ++ op to x1,...,xn.
  subst    : (% , Equation %) -> %
  ++ subst(f, k = g) replaces the kernel k by g formally in f.
  subst    : (% , List Equation %) -> %
  ++ subst(f, [k1 = g1,...,kn = gn]) replaces the kernels k1,...,kn
  ++ by g1,...,gn formally in f.
  subst    : (% , List K, List %) -> %
  ++ subst(f, [k1...kn], [g1,...,gn]) replaces the kernels k1,...,kn
  ++ by g1,...,gn formally in f.
  box      : % -> %
  ++ box(f) returns f with a 'box' around it that prevents f from
  ++ being evaluated when operators are applied to it. For example,
  ++ \spad{log(1)} returns 0, but \spad{log(box 1)}
  ++ returns the formal kernel log(1).
  box      : List % -> %
  ++ box([f1,...,fn]) returns \spad{(f1,...,fn)} with a 'box'

```

```

++ around them that
++ prevents the fi from being evaluated when operators are applied to
++ them, and makes them applicable to a unary operator. For example,
++ \spad{atan(box [x, 2])} returns the formal kernel \spad{atan(x, 2)}.
paren      : % -> %
++ paren(f) returns (f). This prevents f from
++ being evaluated when operators are applied to it. For example,
++ \spad{log(1)} returns 0, but \spad{log(paren 1)} returns the
++ formal kernel log((1)).
paren      : List % -> %
++ paren([f1,...,fn]) returns \spad{(f1,...,fn)}. This
++ prevents the fi from being evaluated when operators are applied to
++ them, and makes them applicable to a unary operator. For example,
++ \spad{atan(paren [x, 2])} returns the formal
++ kernel \spad{atan((x, 2))}.
distribute : % -> %
++ distribute(f) expands all the kernels in f that are
++ formally enclosed by a \spadfunFrom{box}{ExpressionSpace}
++ or \spadfunFrom{paren}{ExpressionSpace} expression.
distribute : (%, %) -> %
++ distribute(f, g) expands all the kernels in f that contain g in their
++ arguments and that are formally
++ enclosed by a \spadfunFrom{box}{ExpressionSpace}
++ or a \spadfunFrom{paren}{ExpressionSpace} expression.
height     : % -> N
++ height(f) returns the highest nesting level appearing in f.
++ Constants have height 0. Symbols have height 1. For any
++ operator op and expressions f1,...,fn, \spad{op(f1,...,fn)} has
++ height equal to \spad{1 + max(height(f1),...,height(fn))}.
mainKernel : % -> Union(K, "failed")
++ mainKernel(f) returns a kernel of f with maximum nesting level, or
++ if f has no kernels (i.e. f is a constant).
kernels    : % -> List K
++ kernels(f) returns the list of all the top-level kernels
++ appearing in f, but not the ones appearing in the arguments
++ of the top-level kernels.
tower      : % -> List K
++ tower(f) returns all the kernels appearing in f, no matter
++ what their levels are.
operators  : % -> List OP
++ operators(f) returns all the basic operators appearing in f,
++ no matter what their levels are.
operator   : OP -> OP
++ operator(op) returns a copy of op with the domain-dependent
++ properties appropriate for %.
belong?    : OP -> Boolean
++ belong?(op) tests if % accepts op as applicable to its
++ elements.
is?        : (%, OP) -> Boolean

GradedAlgebra examples
=====

```

GradedAlgebra(R,E) denotes "E-graded R-algebra". A graded algebra is a graded module together with a degree preserving R-linear map, called the product.

The name "product" is written out in full so inner and outer products with the same mapping type can be distinguished by name.

See Also:

o )show GradedAlgebra

---

See:

=====
IndexedAggregate examples
=====

```

An indexed aggregate is a many-to-one mapping of indices to entries. For example, a one-dimensional-array is an indexed aggregate where the index is an integer. Also, a table is an indexed aggregate where the indices and entries may have any type.

See Also:

o )show IndexedAggregate

---

See:

⇒ “DirectProductCategory” (DIRPCAT) 12 on page 1061

⇒ “LinearAggregate” (LNAGG) 6 on page 467

⇒ “TableAggregate” (TBAGG) 9 on page 861

⇐ “EltableAggregate” (ELTAGG) 3 on page 133

⇐ “HomogeneousAggregate” (HOAGG) 4 on page 242

**Exports:**

any?	coerce	copy	count	elt
empty	empty?	entries	entry?	eq?
eval	every?	fill!	first	hash
index?	indices	latex	less?	map
map!	maxIndex	member?	members	minIndex
more?	parts	qelt	qsetelt!	sample
setelt	size?	swap!	?.?	?~=?
#?	?=?			

**Attributes exported:**

- nil

**Attributes Used:**

- **finiteAggregate** is true if it is an aggregate with a finite number of elements.
- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.

These are directly exported but not implemented:

```
index? : (Index,%) -> Boolean
indices : % -> List Index
```

These are implemented by this category:

```

elt : (%,Index,Entry) -> Entry
entries : % -> List Entry
entry? : (Entry,%) -> Boolean
      if $ has finiteAggregate and Entry has SETCAT
fill! : (%,Entry) -> % if $ has shallowlyMutable
first : % -> Entry if Index has ORDSET
map : ((Entry -> Entry),%) -> %
map! : ((Entry -> Entry),%) -> % if $ has shallowlyMutable
maxIndex : % -> Index if Index has ORDSET
minIndex : % -> Index if Index has ORDSET
swap! : (%,Index,Index) -> Void if $ has shallowlyMutable

```

These exports come from (p242) HomogeneousAggregate(Entry:Type):

```

any? : ((Entry -> Boolean),%) -> Boolean
      if $ has finiteAggregate
coerce : % -> OutputForm if Entry has SETCAT
copy : % -> %
count : (Entry,%) -> NonNegativeInteger
      if Entry has SETCAT and $ has finiteAggregate
count : ((Entry -> Boolean),%) -> NonNegativeInteger
      if $ has finiteAggregate
empty : () -> %
empty? : % -> Boolean
eq? : (%,%) -> Boolean
eval : (%,List Entry,List Entry) -> %
      if Entry has EVALAB Entry and Entry has SETCAT
eval : (%,Entry,Entry) -> %
      if Entry has EVALAB Entry and Entry has SETCAT
eval : (%,Equation Entry) -> %
      if Entry has EVALAB Entry and Entry has SETCAT
eval : (%,List Equation Entry) -> %
      if Entry has EVALAB Entry and Entry has SETCAT
every? : ((Entry -> Boolean),%) -> Boolean
      if $ has finiteAggregate
hash : % -> SingleInteger if Entry has SETCAT
latex : % -> String if Entry has SETCAT
less? : (%,NonNegativeInteger) -> Boolean
member? : (Entry,%) -> Boolean
      if Entry has SETCAT and $ has finiteAggregate

)abbrev category IXAGG IndexedAggregate
++ Author: Michael Monagan; revised by Manuel Bronstein and Richard Jenks
++ Date Created: August 87 through August 88
++ Date Last Updated: April 1991
++ Description:
++ An indexed aggregate is a many-to-one mapping of indices to entries.
++ For example, a one-dimensional-array is an indexed aggregate where
++ the index is an integer. Also, a table is an indexed aggregate
++ where the indices and entries may have any type.

IndexedAggregate(Index: SetCategory, Entry: Type): Category ==
  Join(HomogeneousAggregate(Entry), EltableAggregate(Index, Entry)) with
  entries: % -> List Entry
    ++ entries(u) returns a list of all the entries of aggregate u
    ++ in no assumed order.
    -- to become entries: % -> Entry* and
    -- entries: % -> Iterator(Entry,Entry)
  index?: (Index,% ) -> Boolean
    ++ index?(i,u) tests if i is an index of aggregate u.
  indices: % -> List Index
    ++ indices(u) returns a list of indices of aggregate u in no
    ++ particular order. to become indices:
    -- % -> Index* and indices: % -> Iterator(Index,Index).
-- map: ((Entry,Entry)->Entry,% ,%,Entry) -> %
-- ++ exists c = map(f,a,b,x), i:Index where
-- ++ c.i = f(a(i,x),b(i,x)) | index?(i,a) or index?(i,b)
  if Entry has SetCategory and % has finiteAggregate then
    entry?: (Entry,% ) -> Boolean
      ++ entry?(x,u) tests if x equals \axiom{u . i} for some index i.
  if Index has OrderedSet then
    maxIndex: % -> Index
      ++ maxIndex(u) returns the maximum index i of aggregate u.
      ++ Note that in general,
      ++ \axiom{maxIndex(u) = reduce(max,[i for i in indices u])};
      ++ if u is a list, \axiom{maxIndex(u) = #u}.
    minIndex: % -> Index
      ++ minIndex(u) returns the minimum index i of aggregate u.
      ++ Note that in general,
      ++ \axiom{minIndex(a) = reduce(min,[i for i in indices a])};
      ++ for lists, \axiom{minIndex(a) = 1}.
  first : % -> Entry
    ++ first(u) returns the first element x of u.

```

```

    ++ Note that for collections, \axiom{first}([x,y,...,z]) = x}.
    ++ Error: if u is empty.

if % has shallowlyMutable then
  fill_!: (% ,Entry) -> %
    ++ fill!(u,x) replaces each entry in aggregate u by x.
    ++ The modified u is returned as value.
  swap_!: (% ,Index,Index) -> Void
    ++ swap!(u,i,j) interchanges elements i and j of aggregate u.
    ++ No meaningful value is returned.
add

=====
MonadWithUnit examples
=====

```

MonadWithUnit is the class of multiplicative monads with unit,  
i.e. sets with a binary operation and a unit element.

Axioms:

```

leftIdentity("*: (% ,%) -> % , 1)      1*x=x
rightIdentity("*: (% ,%) -> % , 1)     x*1=x

```

Common Additional Axioms:

unitsKnown - if "recip" says "failed", it PROVES input wasn't a unit

See Also:

o )show MonadWithUnit

**See:**

⇒ “NonAssociativeRing” (NASRING) 9 on page 804

⇐ “Monad” (MONAD) 4 on page 258

**Exports:**

```

1      coerce      hash      latex      one?
recip  leftPower   leftRecip  rightPower  rightRecip
?*?    ?~=?       ?**?     ?=?

```

These are directly exported but not implemented:

```

1 : () -> %
leftRecip : % -> Union(%, "failed")
recip : % -> Union(%, "failed")
rightRecip : % -> Union(%, "failed")

```

These are implemented by this category:

```

leftPower : (%, NonNegativeInteger) -> %
one? : % -> Boolean
rightPower : (%, NonNegativeInteger) -> %
?**? : (%, NonNegativeInteger) -> %

```

These exports come from (p258) Monad():

```

coerce : % -> OutputForm
hash : % -> SingleInteger
latex : % -> String
leftPower : (%, PositiveInteger) -> %
rightPower : (%, PositiveInteger) -> %
?**? : (%, PositiveInteger) -> %
?*? : (%, %) -> %
?~=? : (%, %) -> Boolean
?=? : (%, %) -> Boolean

```

++ Description:
++ MonadWithUnit is the class of multiplicative monads with unit,
++ that is, sets with a binary operation and a unit element.
++
++ Axioms\br
++ \tab{5}leftIdentity("*: (%,%)->%,1) for example, 1*x=x\br
++ \tab{5}rightIdentity("*: (%,%)->%,1) for example, x*1=x
++
++ Common Additional Axioms\br
++ \tab{5}unitsKnown - if "recip" says "failed", it PROVES input wasn't a unit

MonadWithUnit(): Category == Monad with

    1: constant -> %
        ++ \spad{1} returns the unit element, denoted by 1.

    one?: % -> Boolean
        ++ one?(a) tests whether \spad{a} is the unit 1.

    rightPower: (% , NonNegativeInteger) -> %
        ++ rightPower(a,n) returns the \spad{n}-th right power of \spad{a},
        ++ that is, \spad{rightPower(a,n) := rightPower(a,n-1) * a} and
        ++ \spad{rightPower(a,0) := 1}.

    leftPower: (% , NonNegativeInteger) -> %
        ++ leftPower(a,n) returns the \spad{n}-th left power of \spad{a},
        ++ that is, \spad{leftPower(a,n) := a * leftPower(a,n-1)} and
        ++ \spad{leftPower(a,0) := 1}.

    "**": (% , NonNegativeInteger) -> %
        ++ \spad{a**n} returns the \spad{n}-th power of \spad{a},
        ++ defined by repeated squaring.

    recip: % -> Union(%, "failed")
        ++ recip(a) returns an element, which is both a left and a right
        ++ inverse of \spad{a},
        ++ or \spad{"failed"} if such an element doesn't exist or cannot
        ++ be determined (see unitsKnown).

    leftRecip: % -> Union(%, "failed")
        ++ leftRecip(a) returns an element, which is a left inverse of
        ++ \spad{a}, or \spad{"failed"} if such an element doesn't exist
        ++ or cannot be determined (see unitsKnown).

    rightRecip: % -> Union(%, "failed")
        ++ rightRecip(a) returns an element, which is a right inverse of
        ++ \spad{a}, or \spad{"failed"} if such an element doesn't exist
        ++ or cannot be determined (see unitsKnown).

=====
RecursiveAggregate examples
=====

```

A recursive aggregate over a type S is a model for a directed graph containing values of type S. Recursively, a recursive aggregate is a node consisting of a value from S and 0 or more children which are recursive aggregates. A node with no children is called a leaf node. A recursive aggregate may be cyclic for which some operations as noted may go into an infinite loop.

See:

⇒ “BinaryRecursiveAggregate” (BRAGG) 6 on page 436

⇒ “DoublyLinkedAggregate” (DLAGG) 6 on page 456

⇒ “UnaryRecursiveAggregate” (URAGG) 6 on page 569

⇐ “HomogeneousAggregate” (HOAGG) 4 on page 242

**Exports:**

any?	child?	children	coerce	copy
count	cyclic?	distance	empty	empty?
eq?	eval	every?	hash	latex
leaf?	leaves	less?	map	map!
member?	members	more?	nodes	node?
parts	sample	setchildren!	setelt	setvalue!
size?	value	?.value	?~=?	#?
?=?				

**Attributes exported:**

- nil

**Attributes Used:**

- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.

These are directly exported but not implemented:

```
children : % -> List %
cyclic?  : % -> Boolean
distance : (%,% ) -> Integer
nodes    : % -> List %
leaf?    : % -> Boolean
```

```

leaves : % -> List S
node? : (%,% ) -> Boolean if S has SETCAT
setchildren! : (% ,List %) -> % if $ has shallowlyMutable
setvalue! : (% ,S) -> S if $ has shallowlyMutable
value : % -> S

```

These are implemented by this category:

```

child? : (%,% ) -> Boolean if S has SETCAT
setelt : (% ,value ,S) -> S if $ has shallowlyMutable
?.value : (% ,value) -> S

```

These exports come from (p242) HomogeneousAggregate(S:Type):

```

any? : ((S -> Boolean),%) -> Boolean
      if $ has finiteAggregate
coerce : % -> OutputForm if S has SETCAT
copy : % -> %
count : (S,% ) -> NonNegativeInteger
      if S has SETCAT and $ has finiteAggregate
count : ((S -> Boolean),%) -> NonNegativeInteger
      if $ has finiteAggregate
empty : () -> %
empty? : % -> Boolean
eq? : (%,% ) -> Boolean
eval : (% ,List S ,List S) -> %
      if S has EVALAB S and S has SETCAT
eval : (% ,S ,S) -> %
      if S has EVALAB S and S has SETCAT

## — category RCAGG RecursiveAggregate —

```

)abbrev category RCAGG RecursiveAggregate
++ Author: Michael Monagan; revised by Manuel Bronstein and Richard Jenks
++ Date Created: August 87 through August 88
++ Date Last Updated: April 1991
++ Description:
++ A recursive aggregate over a type S is a model for a
++ a directed graph containing values of type S.
++ Recursively, a recursive aggregate is a node
++ consisting of a \spadfun{value} from S and 0 or more \spadfun{children}
++ which are recursive aggregates.
++ A node with no children is called a \spadfun{leaf} node.
++ A recursive aggregate may be cyclic for which some operations as noted
++ may go into an infinite loop.

RecursiveAggregate(S:Type): Category == HomogeneousAggregate(S) with
  children: % -> List %
    ++ children(u) returns a list of the children of aggregate u.
  -- should be % -> %* and also needs children: % -> Iterator(S,S)
  nodes: % -> List %
    ++ nodes(u) returns a list of all of the nodes of aggregate u.
  -- to become % -> %* and also nodes: % -> Iterator(S,S)
  leaf?: % -> Boolean
    ++ leaf?(u) tests if u is a terminal node.
  value: % -> S
    ++ value(u) returns the value of the node u.
  elt: (%,"value") -> S
    ++ elt(u,"value") (also written: \axiom{a. value}) is
    ++ equivalent to \axiom{value(a)}.
  cyclic?: % -> Boolean
    ++ cyclic?(u) tests if u has a cycle.
  leaves: % -> List S
    ++ leaves(t) returns the list of values in obtained by visiting the
    ++ nodes of tree \axiom{t} in left-to-right order.
  distance: (%,% ) -> Integer
    ++ distance(u,v) returns the path length (an integer) from node u to v.
  if S has SetCategory then
    child?: (%,% ) -> Boolean
      ++ child?(u,v) tests if node u is a child of node v.
    node?: (%,% ) -> Boolean
      ++ node?(u,v) tests if node u is contained in node v
      ++ (either as a child, a child of a child, etc.).
  if % has shallowlyMutable then
    setchildren_!: (% ,List % )->%
      ++ setchildren!(u,v) replaces the current children of node u
      ++ with the members of v in left-to-right order.
    setelt: (%,"value",S) -> S
      ++ setelt(a,"value",x) (also written \axiom{a . value := x})

```

```

++ is equivalent to \axiom{setvalue!(a,x)}
setvalue_!: (%,S) -> S
++ setvalue!(u,x) sets the value of node u to x.
add
elt(x,"value") == value x
if % has shallowlyMutable then
setelt(x,"value",y) == setvalue_!(x,y)
if S has SetCategory then
child?(x,l) == member?(x,children(l))

## TwoDimensionalArrayCategory (ARR2CAT)

TwoDimensionalArrayCategory is a general array category which allows different representations and indexing schemes. Rows and columns may be extracted with rows returned as objects of type Row and columns returned as objects of type Col. The index of the 'first' row may be obtained by calling the function 'minRowIndex'. The index of the 'first' column may be obtained by calling the function 'minColIndex'. The index of the first element of a 'Row' is the same as the index of the first column in an array and vice versa.

)abbrev category ARR2CAT TwoDimensionalArrayCategory
++ Date Created: 27 October 1989
++ Date Last Updated: 27 June 1990
++ Keywords: array, data structure
++ Description:
++ Two dimensional array categories and domains

TwoDimensionalArrayCategory(R,Row,Col): Category == Definition where
R   : Type
Row : FiniteLinearAggregate R
Col : FiniteLinearAggregate R

Definition == HomogeneousAggregate(R) with

shallowlyMutable
++ one may destructively alter arrays

finiteAggregate
++ two-dimensional arrays are finite

--% Array creation

new: (NonNegativeInteger,NonNegativeInteger,R) -> %
++ new(m,n,r) is an m-by-n array all of whose entries are r
++
++X arr : ARRAY2 INT := new(5,4,0)

fill_!: (% ,R) -> %
++ fill!(m,r) fills m with r's
++
++X arr : ARRAY2 INT := new(5,4,0)
++X fill!(arr,10)

--% Size inquiries

minRowIndex : % -> Integer
++ minRowIndex(m) returns the index of the 'first' row of the array m
++
++X arr : ARRAY2 INT := new(5,4,10)
++X minRowIndex(arr)

```

```

maxRowIndex : % -> Integer
++ maxRowIndex(m) returns the index of the 'last' row of the array m
++
++X arr : ARRAY2 INT := new(5,4,10)
++X maxRowIndex(arr)

minColIndex : % -> Integer
++ minColIndex(m) returns the index of the 'first' column of the array m
++
++X arr : ARRAY2 INT := new(5,4,10)
++X minColIndex(arr)

maxColIndex : % -> Integer
++ maxColIndex(m) returns the index of the 'last' column of the array m
++
++X arr : ARRAY2 INT := new(5,4,10)
++X maxColIndex(arr)

nrows : % -> NonNegativeInteger
++ nrows(m) returns the number of rows in the array m
++
++X arr : ARRAY2 INT := new(5,4,10)
++X nrows(arr)

ncols : % -> NonNegativeInteger
++ ncols(m) returns the number of columns in the array m
++
++X arr : ARRAY2 INT := new(5,4,10)
++X ncols(arr)

--% Part extractions

elt: (%,Integer,Integer) -> R
++ elt(m,i,j) returns the element in the ith row and jth
++ column of the array m
++ error check to determine if indices are in proper ranges

— BinaryRecursiveAggregate.help —

```
=====
BinaryRecursiveAggregate examples
=====
```

A binary-recursive aggregate has 0, 1 or 2 children and serves as a model for a binary tree or a doubly-linked aggregate structure

See Also:

o )show BinaryRecursiveAggregate

---

**See:**

⇒ “BinaryTreeCategory” (BTCAT) 7 on page 587

⇐ “RecursiveAggregate” (RCAGG) 5 on page 415

**Exports:**

any?	children	child?	coerce	copy
count	cyclic?	distance	empty	empty?
eq?	eval	every?	hash	latex
leaf?	leaves	left	less?	map
map!	member?	members	more?	nodes
node?	parts	right	sample	setchildren!
setelt	setleft!	setright!	setvalue!	size?
value	#?	?=?	?~=?	? .right
? .left	? .value			

**Attributes exported:**

- **nil**

**Attributes Used:**

- **finiteAggregate** is true if it is an aggregate with a finite number of elements.
- **shallowlyMutable** is true if its values have immediate components that are update-able (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.

These are directly exported but not implemented:

```

left : % -> %
right : % -> %
setelt : (% , right , %) -> % if $ has shallowlyMutable
setelt : (% , left , %) -> % if $ has shallowlyMutable
setleft! : (% , %) -> % if $ has shallowlyMutable
setright! : (% , %) -> % if $ has shallowlyMutable

```

These are implemented by this category:

```

children : % -> List %
coerce : % -> OutputForm if S has SETCAT
cyclic? : % -> Boolean
leaf? : % -> Boolean
leaves : % -> List S
member? : (S , %) -> Boolean
           if S has SETCAT and $ has finiteAggregate
nodes : % -> List %
node? : (% , %) -> Boolean if S has SETCAT
#? : % -> NonNegativeInteger if $ has finiteAggregate
=? : (% , %) -> Boolean if S has SETCAT
?.right : (% , right) -> %
?.left : (% , left) -> %

```

These exports come from (p415) RecursiveAggregate(S:Type)

```

any? : ((S -> Boolean) , %) -> Boolean
           if $ has finiteAggregate
child? : (% , %) -> Boolean if S has SETCAT

=====
CancellationAbelianMonoid examples
=====

```

This is an AbelianMonoid with the cancellation property, i.e.

$$a+b = a+c \Rightarrow b=c$$

This is formalised by the partial subtraction operator, which satisfies the Axiom

$$c = a+b \Leftrightarrow c-b = a$$

---

See:

⇒ “Dictionary” (DIAGG) 7 on page 594  
 ⇒ “MultiDictionary” (MDAGG) 7 on page 631  
 ⇐ “BagAggregate” (BGAGG) 5 on page 341  
 ⇐ “Collection” (CLAGG) 5 on page 351

**Exports:**

any?	bag	coerce	construct	convert
copy	count	dictionary	empty	empty?
eq?	eval	every?	extract!	find
hash	insert!	inspect	latex	less?
map	map!	member?	members	more?
parts	reduce	remove	remove!	removeDuplicates
sample	select	select!	size?	#?
?=?	?~=?			

**Attributes exported:**

- **shallowlyMutable** is true if its values have immediate components that are update-

able (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.

- **nil**

#### Attributes Used:

- **finiteAggregate** is true if it is an aggregate with a finite number of elements.

These are directly exported but not implemented:

```
dictionary : List S -> %
remove! : ((S -> Boolean),%) -> % if $ has finiteAggregate
remove! : (S,%) -> % if $ has finiteAggregate
select! : ((S -> Boolean),%) -> % if $ has finiteAggregate
```

These are implemented by this category:

```
coerce : % -> OutputForm if S has SETCAT
construct : List S -> %
copy : % -> %
dictionary : () -> %
```

These exports come from (p341) BagAggregate(S:SetCategory):

```
any? : ((S -> Boolean),%) -> Boolean
      if $ has finiteAggregate
bag : List S -> %
count : (S,%) -> NonNegativeInteger
      if S has SETCAT and $ has finiteAggregate
count : ((S -> Boolean),%) -> NonNegativeInteger
      if $ has finiteAggregate
empty : () -> %
empty? : % -> Boolean
eq? : (%,%) -> Boolean
eval : (%,List S,List S) -> %
      if S has EVALAB S and S has SETCAT
eval : (%,S,S) -> %
      if S has EVALAB S and S has SETCAT
eval : (%,Equation S) -> %
      if S has EVALAB S and S has SETCAT
eval : (%,List Equation S) -> %
      if S has EVALAB S and S has SETCAT
every? : ((S -> Boolean),%) -> Boolean if $ has finiteAggregate
extract! : % -> S
hash : % -> SingleInteger if S has SETCAT
insert! : (S,%) -> %
inspect : % -> S
latex : % -> String if S has SETCAT
```

```

less? : (% , NonNegativeInteger) -> Boolean
map : ((S -> S), %) -> %
map! : ((S -> S), %) -> % if $ has shallowlyMutable
member? : (S, %) -> Boolean
    if S has SETCAT and $ has finiteAggregate
members : % -> List S if $ has finiteAggregate
more? : (% , NonNegativeInteger) -> Boolean
parts : % -> List S if $ has finiteAggregate
sample : () -> %
size? : (% , NonNegativeInteger) -> Boolean
#? : % -> NonNegativeInteger if $ has finiteAggregate
?? : (% , %) -> Boolean if S has SETCAT
?~? : (% , %) -> Boolean if S has SETCAT

```

These exports come from (p351) Collection(S:SetCategory)

```

convert : % -> InputForm if S has KONVERT INFORM
find : ((S -> Boolean), %) -> Union(S, "failed")
reduce : (((S,S) -> S), %) -> S if $ has finiteAggregate

)abbrev category DLAGG DoublyLinkedAggregate
++ Author: Michael Monagan; revised by Manuel Bronstein and Richard Jenks
++ Date Created: August 87 through August 88
++ Date Last Updated: April 1991
++ Description:
++ A doubly-linked aggregate serves as a model for a doubly-linked
++ list, that is, a list which can has links to both next and previous
++ nodes and thus can be efficiently traversed in both directions.

DoublyLinkedAggregate(S:Type): Category == RecursiveAggregate S with
  last: % -> S
    ++ last(l) returns the last element of a doubly-linked aggregate l.
    ++ Error: if l is empty.
  head: % -> %
    ++ head(l) returns the first element of a doubly-linked aggregate l.
    ++ Error: if l is empty.
  tail: % -> %
    ++ tail(l) returns the doubly-linked aggregate l starting at
    ++ its second element.
    ++ Error: if l is empty.
  previous: % -> %
    ++ previous(l) returns the doubly-link list beginning with its previous
    ++ element.
    ++ Error: if l has no previous element.
    ++ Note that \axiom{next(previous(l)) = l}.
  next: % -> %
    ++ next(l) returns the doubly-linked aggregate beginning with its next
    ++ element.
    ++ Error: if l has no next element.
    ++ Note that \axiom{next(l) = rest(l)} and \axiom{previous(next(l)) = l}.
  if % has shallowlyMutable then
    concat_!: (%,% ) -> %
      ++ concat!(u,v) destructively concatenates doubly-linked aggregate v
      ++ to the end of doubly-linked aggregate u.
    setprevious_!: (%,% ) -> %
      ++ setprevious!(u,v) destructively sets the previous node of
      ++ doubly-linked aggregate u to v, returning v.

```

```

setnext_!: (%,% ) -> %
++ setnext!(u,v) destructively sets the next node of doubly-linked
++ aggregate u to v, returning v.

=====
LinearAggregate examples
=====

```

A linear aggregate is an aggregate whose elements are indexed by integers. Examples of linear aggregates are strings, lists, and arrays.

Most of the exported operations for linear aggregates are non-destructive but are not always efficient for a particular aggregate.

For example, `concat` of two lists needs only to copy its first argument, whereas `concat` of two arrays needs to copy both arguments. Most of the operations exported here apply to infinite objects (e.g. streams) as well to finite ones. For finite linear aggregates, see `FiniteLinearAggregate`.

**Exports:**

any?	coerce	concat	construct	convert
copy	count	delete	elt	empty
empty?	entries	entry?	eq?	eval
every?	fill!	find	first	hash
index?	indices	insert	latex	less?
map	map!	maxIndex	member?	members
minIndex	more?	new	parts	qelt
qsetelt!	reduce	remove	removeDuplicates	sample
setelt	size?	swap!	?~=?	#?
?=?	?..?			

**Attributes exported:**

- **nil**

**Attributes Used:**

- **finiteAggregate** is true if it is an aggregate with a finite number of elements.
- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.

These are directly exported but not implemented:

```
concat : (%,%) -> %
concat : List % -> %
delete : (%,Integer) -> %
delete : (%,UniversalSegment Integer) -> %
insert : (%,%,Integer) -> %
map : ((S,S) -> S),%,%) -> %
new : (NonNegativeInteger,S) -> %
setelt : (%,UniversalSegment Integer,S) -> S
        if $ has shallowlyMutable
?..? : (%,UniversalSegment Integer) -> %
```

These are implemented by this category:

```
concat : (%,S) -> %
```

```

concat : (S,%) -> %
index? : (Integer,%) -> Boolean
indices : % -> List Integer
insert : (S,%,Integer) -> %
maxIndex : % -> Integer if Integer has ORDSET

```

These exports come from (p382) IndexedAggregate(Integer,S:Type)

```

=====

## MatrixCategory examples

```
=====
```

MatrixCategory is a general matrix category which allows different representations and indexing schemes. Rows and columns may be extracted with rows returned as objects of type Row and columns returned as objects of type Col. A domain belonging to this category will be shallowly mutable. The index of the 'first' row may be obtained by calling the function minRowIndex. The index of the 'first' column may be obtained by calling the function minColIndex. The index of the first element of a Row is the same as the index of the first column in a matrix and vice versa.

Predicates:

square?(m) returns true if m is a square matrix  
(if m has the same number of rows as columns) and false otherwise.

```
square matrix [[j**i for i in 0..4] for j in 1..5]
```

diagonal?(m) returns true if the matrix m is square and diagonal (i.e. all entries of m not on the diagonal are zero) and false otherwise.

```
diagonal? matrix [[j**i for i in 0..4] for j in 1..5]
```

symmetric?(m) returns true if the matrix m is square and symmetric (i.e.  $\text{m}[i,j] = \text{m}[j,i]$  for all i and j) and false otherwise.

```
symmetric? matrix [[j**i for i in 0..4] for j in 1..5]
```

antisymmetric?(m) returns true if the matrix m is square and antisymmetric (i.e.  $\text{m}[i,j] = -\text{m}[j,i]$  for all i and j) and false otherwise.

```
antisymmetric? matrix [[j**i for i in 0..4] for j in 1..5]
```

Creation

zero(m,n) returns an m-by-n zero matrix.

```
z:Matrix(INT):=zero(3,3)
```

matrix(l) converts the list of lists l to a matrix, where the list of lists is viewed as a list of the rows of the matrix.

```
matrix [[1,2,3],[4,5,6],[7,8,9],[1,1,1]]
```

`scalarMatrix(n,r)` returns an n-by-n matrix with r's on the diagonal and zeroes elsewhere.

```
z:Matrix(INT):=scalarMatrix(3,5)
```

`diagonalMatrix(l)` returns a diagonal matrix with the elements of l on the diagonal.

```
diagonalMatrix [1,2,3]
```

`diagonalMatrix([m1,...,mk])` creates a block diagonal matrix M with block matrices m1,...,mk down the diagonal, with 0 block matrices elsewhere.

More precisely: if  $r_i := \text{nrows } m_i$ ,  $c_i := \text{ncols } m_i$ , then m is an  $(r_1+..+r_k)$  by  $(c_1+..+c_k)$  - matrix with entries  $m.i.j = m_l.(i-r_1-..-r_{l-1}).(j-n_1-..-n_{l-1})$ , if  $(r_1+..+r_{l-1}) < i \leq r_1+..+r_l$  and  $(c_1+..+c_{l-1}) < j \leq c_1+..+c_l$ ,  $m.i.j = 0$  otherwise.

```
diagonalMatrix [matrix [[1,2],[3,4]], matrix [[4,5],[6,7]]]
```

`coerce(col)` converts the column col to a column matrix.

```
coerce([1,2,3])@Matrix(INT)
```

`transpose(r)` converts the row r to a row matrix.

```
transpose([1,2,3])@Matrix(INT)
```

Creation of new matrices from old

`transpose(m)` returns the transpose of the matrix m.

```
m:=matrix [[j**i for i in 0..4] for j in 1..5]
transpose m
```

`squareTop(m)` returns an n-by-n matrix consisting of the first n rows of the m-by-n matrix m. Error: if  $m < n$ .

```
m:=matrix [[j**i for i in 0..2] for j in 1..5]
squareTop m
```

`horizConcat(x,y)` horizontally concatenates two matrices with an equal number of rows. The entries of y appear to the right of the entries of x. Error: if the matrices do not have the same number of rows.

```
m:=matrix [[j**i for i in 0..4] for j in 1..5]
```

```
horizConcat(m,m)
```

`vertConcat(x,y)` vertically concatenates two matrices with an equal number of columns. The entries of `y` appear below of the entries of `x`. Error: if the matrices do not have the same number of columns.

```
m:=matrix [[j**i for i in 0..4] for j in 1..5]
vertConcat(m,m)
```

Part extractions/assignments

`listOfLists(m)` returns the rows of the matrix `m` as a list of lists

```
m:=matrix [[j**i for i in 0..4] for j in 1..5]
listOfLists m
```

`elt(x,rowList,colList)` returns an `m`-by-`n` matrix consisting of elements of `x`, where `m` = # `rowList` and `n` = # `colList`. If `rowList` = [`i<1>`,`i<2>`,...,`i<m>`] and `colList` = [`j<1>`,`j<2>`,...,`j<n>`], then the (`k`,`l`)-th entry of `elt(x,rowList,colList)` is `x(i<k>,j<l>)`.

```
m:=matrix [[j**i for i in 0..4] for j in 1..5]
elt(m,3,3)
```

`setelt(x,rowList,colList,y)` destructively alters the matrix `x`.

If `y` is `m`-by-`n`,  
`rowList` = [`i<1>`,`i<2>`,...,`i<m>`] and  
`colList` = [`j<1>`,`j<2>`,...,`j<n>`],  
then `x(i<k>,j<l>)`  
is set to `y(k,l)` for `k` = 1,...,`m` and `l` = 1,...,`n`

```
m:=matrix [[j**i for i in 0..4] for j in 1..5]
setelt(m,3,3,10)
```

`swapRows!(m,i,j)` interchanges the `i`-th and `j`-th rows of `m`. This destructively alters the matrix.

```
m:=matrix [[j**i for i in 0..4] for j in 1..5]
swapRows!(m,2,4)
```

`swapColumns!(m,i,j)` interchanges the `i`-th and `j`-th columns of `m`. This destructively alters the matrix.

```
m:=matrix [[j**i for i in 0..4] for j in 1..5]
swapColumns!(m,2,4)
```

`subMatrix(x,i1,i2,j1,j2)` extracts the submatrix `[x(i,j)]` where the index `i` ranges from `i1` to `i2`

and the index  $j$  ranges from  $j_1$  to  $j_2$ .

```
m:=matrix [[j**i for i in 0..4] for j in 1..5]
subMatrix(m,1,3,2,4)
```

setsubMatrix( $x, i_1, j_1, y$ ) destructively alters the matrix  $x$ .

Here  $x(i, j)$  is set to  $y(i-i_1+1, j-j_1+1)$  for  
 $i = i_1, \dots, i_1-1+nrows\ y$  and  $j = j_1, \dots, j_1-1+ncols\ y$ .

```
m:=matrix [[j**i for i in 0..4] for j in 1..5]
setsubMatrix!(m,2,2,matrix [[3,3],[3,3]])
```

#### Arithmetic

$x + y$  is the sum of the matrices  $x$  and  $y$ .  
 It is an error if the dimensions are incompatible.

```
m:=matrix [[j**i for i in 0..4] for j in 1..5]
m+m
```

$x - y$  is the difference of the matrices  $x$  and  $y$ .  
 It is an error if the dimensions are incompatible.

```
m:=matrix [[j**i for i in 0..4] for j in 1..5]
m-m
```

$-x$  returns the negative of the matrix  $x$ .

```
m:=matrix [[j**i for i in 0..4] for j in 1..5]
-m
```

$x * y$  is the product of the matrices  $x$  and  $y$ .  
 It is an error if the dimensions are incompatible.

```
m:=matrix [[j**i for i in 0..4] for j in 1..5]
m*m
```

$r*x$  is the left scalar multiple of the scalar  $r$  and the matrix  $x$ .

```
m:=matrix [[j**i for i in 0..4] for j in 1..5]
1/3*m
```

$x * r$  is the right scalar multiple of the scalar  $r$  and the matrix  $x$ .

```
m:=matrix [[j**i for i in 0..4] for j in 1..5]
m*1/3
```

$n * x$  is an integer multiple.

```
m:=matrix [[j**i for i in 0..4] for j in 1..5]
3*m
```

$x * c$  is the product of the matrix  $x$  and the column vector  $c$ .  
It is an error if the dimensions are incompatible.

```
m:=matrix [[j**i for i in 0..4] for j in 1..5]
c:=coerce([1,2,3,4,5])@Matrix(INT)
m *c
```

$r * x$  is the product of the row vector  $r$  and the matrix  $x$ .  
It is an error if the dimensions are incompatible.

```
m:=matrix [[j**i for i in 0..4] for j in 1..5]
r:=transpose([1,2,3,4,5])@Matrix(INT)
r*m
```

$x ** n$  computes a non-negative integral power of the matrix  $x$ .  
It is an error if the matrix is not square.

```
m:=matrix [[j**i for i in 0..4] for j in 1..5]
m**3
```

$\text{exquo}(m,r)$  computes the exact quotient of the elements  
of  $m$  by  $r$ , returning "failed" if this is not possible.

```
m:=matrix [[2**i for i in 2..4] for j in 1..5]
exquo(m,2)
```

$m/r$  divides the elements of  $m$  by  $r$ ,  $r$  must be non-zero.

```
m:=matrix [[2**i for i in 2..4] for j in 1..5]
m/4
```

### Linear algebra

$\text{rowEchelon}(m)$  returns the row echelon form of the matrix  $m$ .

```
rowEchelon matrix [[j**i for i in 0..4] for j in 1..5]
```

$\text{columnSpace}(m)$  returns a sublist of columns of the matrix  $m$

```
columnSpace matrix [[1,2,3],[4,5,6],[7,8,9],[1,1,1]]
```

$\text{rank}(m)$  returns the rank of the matrix  $m$ .

```
rank matrix [[1,2,3],[4,5,6],[7,8,9]]
```

$\text{nullity}(m)$  returns the nullity of the matrix  $m$ . This is  
the dimension of the null space of the matrix  $m$ .

nullity matrix [[1,2,3],[4,5,6],[7,8,9]]

nullSpace(m) returns a basis for the null space of the matrix m.

nullSpace matrix [[1,2,3],[4,5,6],[7,8,9]]

determinant(m) returns the determinant of the matrix m.  
It is an error if the matrix is not square.

determinant matrix [[j\*\*i for i in 0..4] for j in 1..5]

minordet(m) computes the determinant of the matrix m using minors.  
It is an error if the matrix is not square.

minordet matrix [[j\*\*i for i in 0..4] for j in 1..5]

pfaffian(m) returns the Pfaffian of the matrix m.  
It is an error if the matrix is not antisymmetric

pfaffian [[0,1,0,0],[-1,0,0,0],[0,0,0,1],[0,0,-1,0]]

inverse(m) returns the inverse of the matrix m.  
If the matrix is not invertible, "failed" is returned.  
It is an error if the matrix is not square.

inverse matrix [[j\*\*i for i in 0..4] for j in 1..5]

m\*\*n computes an integral power of the matrix m.  
It is an error if matrix is not square or  
if the matrix is square but not invertible.

(matrix [[j\*\*i for i in 0..4] for j in 1..5]) \*\* 2

---

We define three categories for matrices

- MatrixCategory is the category of all matrices
- RectangularMatrixCategory is the category of all matrices of a given dimension
- SquareMatrixCategory inherits from RectangularMatrixCategory

The Matrix domain is the domain of all matrices.

All three domains share the same representation, inherited from Matrix. Most algorithms are only implemented for Matrix but implemented in separate packages.

- MatrixLinearAlgebraFunctions is the top-level package that calls the other packages

- `InnerMatrixLinearAlgebraFunctions` contains implementations that work over a `Field`
- `InnerMatrixQuotientFieldFunctions` contain implementations that work over a quotient field

Implementations that rely on the representation of matrices used in `Matrix` should be put into these packages.

**Attributes Exported:**

- `finiteAggregate` is true if it is an aggregate with a finite number of elements.
- `shallowlyMutable` is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the `shallowlyMutable` proper.
- `nil`

These are directly exported but not implemented:

```
determinant : % -> R if R has commutative *
inverse : % -> Union(%, "failed") if R has FIELD
minordet : % -> R if R has commutative *
nullity : % -> NonNegativeInteger if R has INTDOM
nullSpace : % -> List Col if R has INTDOM
```

```

rowEchelon : % -> % if R has EUCDOM
rank : % -> NonNegativeInteger if R has INTDOM

```

These are implemented by this category:

```

antisymmetric? : % -> Boolean
coerce : Col -> %
columnSpace : % -> List Col if R has EUCDOM
diagonal? : % -> Boolean
diagonalMatrix : List % -> %
diagonalMatrix : List R -> %

```

++ Authors: Grabmeier, Gschnitzer, Williamson, Gabriel Dos Reis
++ Date Created: 1987
++ Date Last Updated: July 1990
++ Description:
++ \spadtype{MatrixCategory} is a general matrix category which allows
++ different representations and indexing schemes. Rows and
++ columns may be extracted with rows returned as objects of
++ type Row and cols returned as objects of type Col.
++ A domain belonging to this category will be shallowly mutable.
++ The index of the 'first' row may be obtained by calling the
++ function \spadfun{minRowIndex}. The index of the 'first' column may
++ be obtained by calling the function \spadfun{minColIndex}. The index of
++ the first element of a Row is the same as the index of the
++ first column in a matrix and vice versa.

```

```

=====
PolynomialSetCategory examples
=====

```

A category for finite subsets of a polynomial ring. Such a set is only regarded as a set of polynomials and not identified to the ideal it generates. So two distinct sets may generate the same the ideal. Furthermore, for  $R$  being an integral domain, a set of polynomials may be viewed as a representation of the ideal it generates in the polynomial ring  $(R)^{-1}P$ , or the set of its zeros (described for instance by the radical of the previous ideal, or a split of the associated affine variety) and so on. So this category provides operations about those different notions.

```

)abbrev category PSETCAT PolynomialSetCategory
++ Author: Marc Moreno Maza
++ Date Created: 04/26/1994
++ Date Last Updated: 12/15/1998
++ Description:
++ A category for finite subsets of a polynomial ring.
++ Such a set is only regarded as a set of polynomials and not
++ identified to the ideal it generates. So two distinct sets may
++ generate the same the ideal. Furthermore, for \spad{R} being an
++ integral domain, a set of polynomials may be viewed as a representation
++ of the ideal it generates in the polynomial ring \spad{(R)^(-1) P},
++ or the set of its zeros (described for instance by the radical of the
++ previous ideal, or a split of the associated affine variety) and so on.
++ So this category provides operations about those different notions.

PolynomialSetCategory(R:Ring, E:OrderedAbelianMonoidSup, _
  VarSet:OrderedSet, P:RecursivePolynomialCategory(R,E,VarSet)): Category ==
  Join(SetCategory,Collection(P),CoercibleTo(List(P))) with
    finiteAggregate
    retractIfCan : List(P) -> Union($,"failed")
      ++ \axiom{retractIfCan(lp)} returns an element of the domain
      ++ whose elements are the members of \axiom{lp} if such an element
      ++ exists, otherwise \axiom{"failed"} is returned.
    retract : List(P) -> $
      ++ \axiom{retract(lp)} returns an element of the domain whose elements
      ++ are the members of \axiom{lp} if such an element exists, otherwise
      ++ an error is produced.
    mvar : $ -> VarSet
      ++ \axiom{mvar(ps)} returns the main variable of the non constant
      ++ polynomial with the greatest main variable, if any, else an
      ++ error is returned.
    variables : $ -> List VarSet
      ++ \axiom{variables(ps)} returns the decreasingly sorted list of the
      ++ variables which are variables of some polynomial in \axiom{ps}.
    mainVariables : $ -> List VarSet
      ++ \axiom{mainVariables(ps)} returns the decreasingly sorted list
      ++ of the variables which are main variables of some polynomial
      ++ in \axiom{ps}.
    mainVariable? : (VarSet,$) -> Boolean
      ++ \axiom{mainVariable?(v,ps)} returns true iff \axiom{v} is the
      ++ main variable of some polynomial in \axiom{ps}.
    collectUnder : ($,VarSet) -> $
      ++ \axiom{collectUnder(ps,v)} returns the set consisting of the

```

```

    ++ polynomials of \axiom{ps} with main variable less than \axiom{v}.
collect : ($,VarSet) -> $
    ++ \axiom{collect(ps,v)} returns the set consisting of the
    ++ polynomials of \axiom{ps} with \axiom{v} as main variable.
collectUpper : ($,VarSet) -> $
    ++ \axiom{collectUpper(ps,v)} returns the set consisting of the
    ++ polynomials of \axiom{ps} with main variable greater
    ++ than \axiom{v}.
sort : ($,VarSet) -> Record(under:$,floor:$,upper:$)
    ++ \axiom{sort(v,ps)} returns \axiom{us,vs,ws} such that \axiom{us}
    ++ is \axiom{collectUnder(ps,v)}, \axiom{vs} is \axiom{collect(ps,v)}
    ++ and \axiom{ws} is \axiom{collectUpper(ps,v)}.
trivialIdeal?: $ -> Boolean
    ++ \axiom{trivialIdeal?(ps)} returns true iff \axiom{ps} does
    ++ not contain non-zero elements.
if R has IntegralDomain
then
    roughBase? : $ -> Boolean
        ++ \axiom{roughBase?(ps)} returns true iff for every pair
        ++ \axiom{p,q} of polynomials in \axiom{ps} their leading
        ++ monomials are relatively prime.
    roughSubIdeal? : ($,$) -> Boolean
        ++ \axiom{roughSubIdeal?(ps1,ps2)} returns true iff it can proved
        ++ that all polynomials in \axiom{ps1} lie in the ideal generated
        ++ by \axiom{ps2} in \axiom{\axiom{(R)^(-1) P}} without computing
        ++ Groebner bases.
    roughEqualIdeals? : ($,$) -> Boolean
        ++ \axiom{roughEqualIdeals?(ps1,ps2)} returns true iff it can
        ++ proved that \axiom{ps1} and \axiom{ps2} generate the same ideal
        ++ in \axiom{(R)^(-1) P} without computing Groebner bases.
    roughUnitIdeal? : $ -> Boolean
        ++ \axiom{roughUnitIdeal?(ps)} returns true iff \axiom{ps} contains
        ++ some non null element lying in the base ring \axiom{R}.
    headRemainder : (P,$) -> Record(num:P,den:R)
        ++ \axiom{headRemainder(a,ps)} returns \axiom{[b,r]} such that the
        ++ leading monomial of \axiom{b} is reduced in the sense of
        ++ Groebner bases w.r.t. \axiom{ps} and \axiom{r*a - b} lies in
        ++ the ideal generated by \axiom{ps}.
    remainder : (P,$) -> Record(rnum:R,polnum:P,den:R)
        ++ \axiom{remainder(a,ps)} returns \axiom{[c,b,r]} such that
        ++ \axiom{b} is fully reduced in the sense of Groebner bases
        ++ w.r.t. \axiom{ps}, \axiom{r*a - c*b} lies in the ideal
        ++ generated by \axiom{ps}. Furthermore, if \axiom{R} is a
        ++ gcd-domain, \axiom{b} is primitive.
    rewriteIdealWithHeadRemainder : (List(P),$) -> List(P)
        ++ \axiom{rewriteIdealWithHeadRemainder(lp,cs)} returns \axiom{lr}
        ++ such that the leading monomial of every polynomial in \axiom{lr}
        ++ is reduced in the sense of Groebner bases w.r.t. \axiom{cs}
        ++ and \axiom{lp,cs} and \axiom{(lr,cs)} generate the same
        ++ ideal in \axiom{(R)^(-1) P}.

```

```

rewriteIdealWithRemainder : (List(P), $) -> List(P)
  ++ \axiom{rewriteIdealWithRemainder}(lp,cs)} returns \axiom{lr}
  ++ such that every polynomial in \axiom{lr} is fully reduced in
  ++ the sense of Groebner bases w.r.t. \axiom{cs} and
  ++ \axiom{(lp,cs)} and \axiom{(lr,cs)} generate the same ideal
  ++ in \axiom{(R)^(-1) P}.
triangular? : $ -> Boolean
  ++ \axiom{triangular?(ps)} returns true iff \axiom{ps} is a
  ++ triangular set, i.e. two distinct polynomials have distinct
  ++ main variables and no constant lies in \axiom{ps}.

```
=====
PriorityQueueAggregate examples
=====
```

A priority queue is a bag of items from an ordered set where the item extracted is always the maximum element.

See Also:

o )show PriorityQueueAggregate

---

**See:**

⇒ “OrderedMultisetAggregate” (OMSAGG) [9](#) on page [827](#)

⇐ “BagAggregate” (BGAGG) [5](#) on page [341](#)

**Exports:**

any?	bag	copy	coerce	count
empty	empty?	eq?	eval	every?
extract!	hash	insert!	inspect	latex
less?	map	map!	max	member?
members	merge	merge!	more?	parts
sample	size?	#?	?=?	?~=?

**Attributes Exported:**

- **finiteAggregate** is true if it is an aggregate with a finite number of elements.
- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.

These are directly exported but not implemented:

```
max : % -> S
merge : (%,% ) -> %
merge! : (%,% ) -> %
```

These exports come from (p341) BagAggregate(S:OrderedSet):

```

any? : ((S -> Boolean),%) -> Boolean
      if $ has finiteAggregate
bag : List S -> %
coerce : % -> OutputForm if S has SETCAT

=====
SetAggregate examples
=====
```

A set category lists a collection of set-theoretic operations useful for both finite sets and multisets. Note however that finite sets are distinct from multisets. Although the operations defined for set categories are common to both, the relationship between the two cannot be described by inclusion or inheritance.

**Exports:**

any?	brace	coerce	construct	convert
copy	count	difference	empty	empty?
eq?	eval	every?	find	hash
intersect	latex	less?	map	map!
member?	members	more?	parts	reduce
remove	removeDuplicates	sample	select	set
size?	subset?	symmetricDifference	union	#?
?<?	?=?	?~=?		

**Attributes Exported:**

- **partiallyOrderedSet** is true if a set with  $<$  which is transitive, but  $\text{not}(a < b \text{ or } a = b)$  does not necessarily imply  $b < a$ .

- **nil**

These are directly exported but not implemented:

```
brace : List S -> %
brace : () -> %
difference : (%,% ) -> %
intersect : (%,% ) -> %
set : List S -> %
set : () -> %
subset? : (%,% ) -> Boolean
union : (%,% ) -> %
?<? : (%,% ) -> Boolean
```

These are implemented by this category:

```
difference : (% , S) -> %
symmetricDifference : (% , %) -> %
union : (S , %) -> %
union : (% , S) -> %
```

These exports come from (p170) SetCategory():

```
coerce : % -> OutputForm
hash : % -> SingleInteger
latex : % -> String
?=? : (% , %) -> Boolean
?~=? : (% , %) -> Boolean
```

These exports come from (p351) Collection(S:SetCategory):

```
any? : ((S -> Boolean) , %) -> Boolean
  if $ has finiteAggregate

++ Author: Michael Monagan; revised by Manuel Bronstein and Richard Jenks
++ Date Created: August 87 through August 88
++ Date Last Updated: 14 Oct, 1993 by RSS
++ Description:
++ A set category lists a collection of set-theoretic operations
++ useful for both finite sets and multisets.

```

```

++ Note however that finite sets are distinct from multisets.
++ Although the operations defined for set categories are
++ common to both, the relationship between the two cannot
++ be described by inclusion or inheritance.

```

```

SetAggregate(S:SetCategory):
  Category == Join(SetCategory, Collection(S)) with
  partiallyOrderedSet
  "<"      : (%, %) -> Boolean
  ++ s < t returns true if all elements of set aggregate s are also
  ++ elements of set aggregate t.
  brace    : () -> %
  ++ brace()$D (otherwise written {}$D)
  ++ creates an empty set aggregate of type D.
  ++ This form is considered obsolete. Use \axiomFun{set} instead.
  brace    : List S -> %
  ++ brace([x,y,...,z])
  ++ creates a set aggregate containing items x,y,...,z.
  ++ This form is considered obsolete. Use \axiomFun{set} instead.
  set      : () -> %
  ++ set()$D creates an empty set aggregate of type D.
  set      : List S -> %
  ++ set([x,y,...,z]) creates a set aggregate containing items x,y,...,z.
  intersect: (%, %) -> %
  ++ intersect(u,v) returns the set aggregate w consisting of
  ++ elements common to both set aggregates u and v.
  ++ Note that equivalent to the notation (not currently supported)
  ++ {x for x in u | member?(x,v)}.
  difference : (%, %) -> %
  ++ difference(u,v) returns the set aggregate w consisting of
  ++ elements in set aggregate u but not in set aggregate v.
  ++ If u and v have no elements in common, \axiom{difference(u,v)}
  ++ returns a copy of u.
  ++ Note that equivalent to the notation (not currently supported)
  ++ \axiom{{x for x in u | not member?(x,v)}}.
  difference : (%, S) -> %
  ++ difference(u,x) returns the set aggregate u with element x removed.
  ++ If u does not contain x, a copy of u is returned.
  ++ Note that \axiom{difference(s, x) = difference(s, {x})}.
  symmetricDifference : (%, %) -> %
  ++ symmetricDifference(u,v) returns the set aggregate of elements x
  ++ which are members of set aggregate u or set aggregate v but
  ++ not both. If u and v have no elements in common,
  ++ \axiom{symmetricDifference(u,v)} returns a copy of u.
  ++ Note that \axiom{symmetricDifference(u,v) =
  ++ union(difference(u,v),difference(v,u))}
  subset?    : (%, %) -> Boolean
  ++ subset?(u,v) tests if u is a subset of v.
  ++ Note that equivalent to
  ++ \axiom{reduce(and,{member?(x,v) for x in u},true,false)}.

```

```

union      : (% , %) -> %
  ++ union(u,v) returns the set aggregate of elements which are members
  ++ of either set aggregate u or v.
union      : (% , S) -> %
  ++ union(u,x) returns the set aggregate u with the element x added.
  ++ If u already contains x, \axiom{union(u,x)} returns a copy of u.
union      : (S , %) -> %
  ++ union(x,u) returns the set aggregate u with the element x added.
  ++ If u already contains x, \axiom{union(x,u)} returns a copy of u.

=====
UnaryRecursiveAggregate examples
=====

```

A unary-recursive aggregate is a one where nodes may have either 0 or 1 children. This aggregate models, though not precisely, a linked list possibly with a single cycle.

A node with one children models a non-empty list, with the value of the list designating the head, or first, of the list, and the child designating the tail, or rest, of the list. A node with no child then designates the empty list. Since these aggregates are recursive aggregates, they may be cyclic.

— category URAGG UnaryRecursiveAggregate —

```

)abbrev category URAGG UnaryRecursiveAggregate
++ Author: Michael Monagan; revised by Manuel Bronstein and Richard Jenks
++ Date Created: August 87 through August 88
++ Date Last Updated: April 1991
++ Description:
++ A unary-recursive aggregate is a one where nodes may have either
++ 0 or 1 children.
++ This aggregate models, though not precisely, a linked
++ list possibly with a single cycle.
++ A node with one children models a non-empty list, with the
++ \spadfun{value} of the list designating the head, or \spadfun{first},
++ of the list, and the child designating the tail, or \spadfun{rest},
++ of the list. A node with no child then designates the empty list.
++ Since these aggregates are recursive aggregates, they may be cyclic.

UnaryRecursiveAggregate(S:Type): Category == RecursiveAggregate S with
concat: (% ,%) -> %
    ++ concat(u,v) returns an aggregate w consisting of the elements of u
    ++ followed by the elements of v.
    ++ Note that \axiom{v = rest(w,#a)}.
concat: (S,% ) -> %
    ++ concat(x,u) returns aggregate consisting of x followed by
    ++ the elements of u.
    ++ Note that if \axiom{v = concat(x,u)} then \axiom{x = first v}
    ++ and \axiom{u = rest v}.
first: % -> S
    ++ first(u) returns the first element of u
    ++ (equivalently, the value at the current node).
elt: (% ,"first") -> S
    ++ elt(u,"first") (also written: \axiom{u . first})
    ++ is equivalent to first u.
first: (% ,NonNegativeInteger) -> %
    ++ first(u,n) returns a copy of the first n (\axiom{n >= 0})
    ++ elements of u.
rest: % -> %
    ++ rest(u) returns an aggregate consisting of all but the first
    ++ element of u
    ++ (equivalently, the next node of u).

```

```

elt: (%,"rest") -> %
  ++ elt(%,"rest") (also written: \axiom{u.rest}) is
  ++ equivalent to \axiom{rest u}.
rest: (% ,NonNegativeInteger) -> %
  ++ rest(u,n) returns the \axiom{n}th (n >= 0) node of u.
  ++ Note that \axiom{rest(u,0) = u}.
last: % -> S
  ++ last(u) return the last element of u.
  ++ Note that for lists, \axiom{last(u)=u . (maxIndex u)=u . (# u - 1)}.
elt: (%,"last") -> S
  ++ elt(u,"last") (also written: \axiom{u . last}) is equivalent
  ++ to last u.
last: (% ,NonNegativeInteger) -> %
  ++ last(u,n) returns a copy of the last n (\axiom{n >= 0}) nodes of u.
  ++ Note that \axiom{last(u,n)} is a list of n elements.
tail: % -> %
  ++ tail(u) returns the last node of u.
  ++ Note that if u is \axiom{shallowlyMutable},
  ++ \axiom{setrest(tail(u),v) = concat(u,v)}.
second: % -> S
  ++ second(u) returns the second element of u.
  ++ Note that \axiom{second(u) = first(rest(u))}.
third: % -> S
  ++ third(u) returns the third element of u.
  ++ Note that \axiom{third(u) = first(rest(rest(u)))}.
cycleEntry: % -> %
  ++ cycleEntry(u) returns the head of a top-level cycle contained in
  ++ aggregate u, or \axiom{empty()} if none exists.
cycleLength: % -> NonNegativeInteger
  ++ cycleLength(u) returns the length of a top-level cycle
  ++ contained in aggregate u, or 0 is u has no such cycle.
cycleTail: % -> %
  ++ cycleTail(u) returns the last node in the cycle, or
  ++ empty if none exists.
if % has shallowlyMutable then
concat_!: (% ,%) -> %
  ++ concat!(u,v) destructively concatenates v to the end of u.
  ++ Note that \axiom{concat!(u,v) = setlast_!(u,v)}.
concat_!: (% ,S) -> %
  ++ concat!(u,x) destructively adds element x to the end of u.
  ++ Note that \axiom{concat!(a,x) = setlast!(a,[x])}.
cycleSplit_!: % -> %
  ++ cycleSplit!(u) splits the aggregate by dropping off the cycle.
  ++ The value returned is the cycle entry, or nil if none exists.
  ++ For example, if \axiom{w = concat(u,v)} is the cyclic list where
  ++ v is the head of the cycle, \axiom{cycleSplit!(w)} will drop v
  ++ off w thus destructively changing w to u, and returning v.
setfirst_!: (% ,S) -> S
  ++ setfirst!(u,x) destructively changes the first element of a to x.
setelt: (% ,"first",S) -> S

```

```

    ++ setelt(u,"first",x) (also written: \axiom{u.first := x}) is
    ++ equivalent to \axiom{setfirst!(u,x)}.
setrest_!: (%,% ) -> %
    ++ setrest!(u,v) destructively changes the rest of u to v.
setelt: (%,"rest",%) -> %
    ++ setelt(u,"rest",v) (also written: \axiom{u.rest := v}) is
    ++ equivalent to \axiom{setrest!(u,v)}.
setlast_!: (% ,S) -> S
    ++ setlast!(u,x) destructively changes the last element of u to x.
setelt: (%,"last",S) -> S
    ++ setelt(u,"last",x) (also written: \axiom{u.last := b})
    ++ is equivalent to \axiom{setlast!(u,v)}.
split_!: (% ,Integer) -> %
    ++ split!(u,n) splits u into two aggregates: \axiom{v = rest(u,n)}
    ++ and \axiom{w = first(u,n)}, returning \axiom{v}.
    ++ Note that afterwards \axiom{rest(u,n)} returns \axiom{empty()}.

=====
Dictionary examples
=====
```

A dictionary is an aggregate in which entries can be inserted, searched for and removed. Duplicates are thrown away on insertion. This category models the usual notion of dictionary which involves large amounts of data where copying is impractical.

Principal operations are thus destructive (non-copying) ones.

See Also:

```
o )show Dictionary
```

---

See:

```
⇒ “FiniteSetAggregate” (FSAGG) 8 on page 683
⇒ “KeyedDictionary” (KDAGG) 8 on page 692
← “DictionaryOperations” (DIOPS) 6 on page 449
```

**Exports:**

any?	bag	coerce	construct	convert
copy	count	dictionary	empty	empty?
eq?	eval	every?	extract!	find
hash	insert!	inspect	latex	less?
map	map!	member?	members	more?
parts	reduce	remove	remove!	removeDuplicates
sample	select	select!	size?	#?
?^=?	?=?			

**Attributes exported:**

- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.

- nil

#### Attributes Used:

- **finiteAggregate** is true if it is an aggregate with a finite number of elements.

These are implemented by this category:

```
dictionary : List S -> %
select! : ((S -> Boolean),%) -> % if $ has finiteAggregate
?? : (%,%) -> Boolean if S has SETCAT
remove! : ((S -> Boolean),%) -> % if $ has finiteAggregate
```

These exports come from (p449) DictionaryOperations(S:SetCategory):

```
any? : ((S -> Boolean),%) -> Boolean
      if $ has finiteAggregate
bag : List S -> %
coerce : % -> OutputForm if S has SETCAT

ExtensibleLinearAggregate examples
=====

```

An extensible aggregate is one which allows insertion and deletion of entries. These aggregates are models of lists and streams which are represented by linked structures so as to make insertion, deletion, and concatenation efficient. However, access to elements of these extensible aggregates is generally slow since access is made from the end. See `FlexibleArray` for an exception.

⇒ “ListAggregate” (LSAGG) 8 on page 722  
 ⇐ “LinearAggregate” (LNAGG) 6 on page 467

**Exports:**

any?	coerce	concat	concat!	construct
copy	convert	count	delete	delete!
elt	empty	empty?	entries	entry?
eval	every?	eq?	fill!	find
first	hash	index?	indices	insert
insert!	latex	less?	map	map!
maxIndex	member?	members	merge!	minIndex
more?	new	parts	qelt	qsetelt!
reduce	remove	remove!	removeDuplicates	removeDuplicates!
sample	select	select!	setelt	size?
swap!	#!	?=?	?..?	?^=?

**Attributes Exported:**

- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.
- **nil**

These are directly exported but not implemented:

```
concat! : (% , S) -> %
delete! : (% , Integer) -> %
delete! : (% , UniversalSegment Integer) -> %
insert! : (% , % , Integer) -> %
insert! : (S , % , Integer) -> %
merge! : (((S , S) -> Boolean) , % , % ) -> %
remove! : ((S -> Boolean) , % ) -> %
removeDuplicates! : % -> % if S has SETCAT
select! : ((S -> Boolean) , % ) -> %
```

These are implemented by this category:

```
concat : (% , % ) -> %
concat : (% , S) -> %
concat! : (% , % ) -> %
delete : (% , Integer) -> %
delete : (% , UniversalSegment Integer) -> %
insert : (% , % , Integer) -> %
insert : (S , % , Integer) -> %
merge! : (% , % ) -> % if S has ORDSET
remove : ((S -> Boolean) , % ) -> % if $ has finiteAggregate
remove : (S , % ) -> % if S has SETCAT and $ has finiteAggregate
remove! : (S , % ) -> % if S has SETCAT
removeDuplicates : % -> %
    if S has SETCAT and $ has finiteAggregate
select : ((S -> Boolean) , % ) -> % if $ has finiteAggregate
```

These exports come from (p467) LinearAggregate(S:Type):

=====
FiniteLinearAggregate examples
=====

```

A finite linear aggregate is a linear aggregate of finite length. The finite property of the aggregate adds several exports to the list of exports from LinearAggregate such as reverse, sort, and so on.

See Also:  
o )show FiniteLinearAggregate

---

See:

⇒ “OneDimensionalArrayAggregate” (A1AGG) 8 on page 747

⇒ “ListAggregate” (LSAGG) 8 on page 722

⇐ “LinearAggregate” (LNAGG) 6 on page 467

⇐ “OrderedSet” (ORDSET) 4 on page 278

### Exports:

any?	coerce	concat	construct	convert
copy	copyInto!	count	delete	elt
empty	empty?	entries	entry?	eq?
eval	every?	fill!	find	first
hash	index?	indices	insert	latex
less?	map	map!	max	maxIndex
member?	members	merge	min	minIndex
more?	new	parts	position	qelt
qsetelt!	reduce	remove	removeDuplicates	reverse
reverse!	sample	select	setelt	size?
sort	sort!	sorted?	swap!	#?
?.?	?<?	?<=?	?=?	?>?
?>=?	?~=?			

### Attributes Exported:

- **finiteAggregate** is true if it is an aggregate with a finite number of elements.
- **nil**

### Attributes Used:

- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.

These are directly exported but not implemented:

```
copyInto! : (%,%,Integer) -> %
           if $ has shallowlyMutable
merge : (((S,S) -> Boolean),%,%) -> %
sorted? : (((S,S) -> Boolean),%) -> Boolean
position : (S,%,Integer) -> Integer if S has SETCAT
position : ((S -> Boolean),%) -> Integer
reverse! : % -> % if $ has shallowlyMutable
sort! : (((S,S) -> Boolean),%) -> %
         if $ has shallowlyMutable
```

These are implemented by this category:

```
merge : (%,%) -> % if S has ORDSET
```

```

position : (S,%) -> Integer if S has SETCAT
reverse  : % -> %
sort     : % -> % if S has ORDSET
sort     : ((S,S) -> Boolean),% -> %
sorted?  : % -> Boolean if S has ORDSET
sort!    : % -> %
          if S has ORDSET and $ has shallowlyMutable

```

These exports come from (p467) LinearAggregate(S:Type):

```

any? : ((S -> Boolean),%) -> Boolean
      if $ has finiteAggregate
coerce : % -> OutputForm if S has SETCAT
concat : List % -> %

++ Description:
++ A finite linear aggregate is a linear aggregate of finite length.
++ The finite property of the aggregate adds several exports to the
++ list of exports from \spadtype{LinearAggregate} such as
++ \spadfun{reverse}, \spadfun{sort}, and so on.

FiniteLinearAggregate(S:Type): Category == LinearAggregate S with
finiteAggregate
merge: ((S,S)->Boolean,%,% ) -> %
  ++ merge(p,a,b) returns an aggregate c which merges \axiom{a} and b.
  ++ The result is produced by examining each element x of \axiom{a}
  ++ and y of b successively. If \axiom{p(x,y)} is true, then x is
  ++ inserted into the result; otherwise y is inserted. If x is
  ++ chosen, the next element of \axiom{a} is examined, and so on.
  ++ When all the elements of one aggregate are examined, the
  ++ remaining elements of the other are appended.
  ++ For example, \axiom{merge(<, [1,3], [2,7,5])} returns
  ++ \axiom{[1,2,3,7,5]}.
reverse: % -> %
  ++ reverse(a) returns a copy of \axiom{a} with elements
  ++ in reverse order.
sort: ((S,S)->Boolean,% ) -> %
  ++ sort(p,a) returns a copy of \axiom{a} sorted using total ordering
  ++ predicate p.
sorted?: ((S,S)->Boolean,% ) -> Boolean
  ++ sorted?(p,a) tests if \axiom{a} is sorted according to predicate p.
position: (S->Boolean, %) -> Integer
  ++ position(p,a) returns the index i of the first x in \axiom{a}
  ++ such that \axiom{p(x)} is true, and \axiom{minIndex(a) - 1}
  ++ if there is no such x.
if S has SetCategory then
  position: (S, %) -> Integer
    ++ position(x,a) returns the index i of the first occurrence of
    ++ x in a, and \axiom{minIndex(a) - 1} if there is no such x.
  position: (S,% ,Integer) -> Integer
    ++ position(x,a,n) returns the index i of the first occurrence of
    ++ x in \axiom{a} where \axiom{i >= n}, and \axiom{minIndex(a) - 1}
    ++ if no such x is found.
```

```

if S has OrderedSet then
  OrderedSet
  merge: (%,% ) -> %
    ++ merge(u,v) merges u and v in ascending order.
    ++ Note that \axiom{merge(u,v) = merge(<=,u,v)}.
  sort: % -> %
    ++ sort(u) returns an u with elements in ascending order.
    ++ Note that \axiom{sort(u) = sort(<=,u)}.
  sorted?: % -> Boolean
    ++ sorted?(u) tests if the elements of u are in ascending order.
if % has shallowlyMutable then
  copyInto_!: (%,% ,Integer) -> %
    ++ copyInto!(u,v,i) returns aggregate u containing a copy of
    ++ v inserted at element i.
  reverse_!: % -> %
    ++ reverse!(u) returns u with its elements in reverse order.
  sort_!: ((S,S)->Boolean,% ) -> %
    ++ sort!(p,u) returns u with its elements ordered by p.
if S has OrderedSet then sort_!: % -> %
  ++ sort!(u) returns u with its elements in ascending order.
add
if S has SetCategory then
  position(x:S, t:% ) == position(x, t, minIndex t)

if S has OrderedSet then
-- sorted? l == sorted?(_<$S, l)
sorted? l == sorted?((x,y) +-> x < y or x = y, l)
merge(x, y) == merge(_<$S, x, y)
sort l == sort(_<$S, l)

if % has shallowlyMutable then
reverse x == reverse_! copy x
sort(f, l) == sort_!(f, copy l)

if S has OrderedSet then
sort_! l == sort_!(_<$S, l)

---

See:

⇐ “Group” (GROUP) 6 on page 462

**Exports:**

```

1      coerce  commutator  conjugate  cycle
cycles eval    hash        inv        latex
max    min     one?       orbit     recip
sample ??     ??        ?~=?     ?**?
?<?   ?<=?   ?>?       ?>=?     ?*?
?/?    ?=?

```

**Attributes Exported:**

- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has `unitsKnown` means that the operation `recip` can only return “failed” if its argument is not a unit.

These are directly exported but not implemented:

```

cycle : List S -> %
cycles : List List S -> %
eval : (%,S) -> S
orbit : (%,S) -> Set S
?<? : (%,% ) -> Boolean
?/? : (%,S) -> S

```

These exports come from (p462) `Group()`:

```

1 : () -> %
coerce : % -> OutputForm
commutator : (%,% ) -> %
conjugate : (%,% ) -> %
hash : % -> SingleInteger
inv : % -> %
latex : % -> String
one? : % -> Boolean
recip : % -> Union(%, "failed")
sample : () -> %
?/? : (%,% ) -> %
?? : (% , NonNegativeInteger) -> %
?? : (% , PositiveInteger) -> %
?? : (% , Integer) -> %
?* : (%,% ) -> %
?= : (%,% ) -> Boolean
?~=? : (%,% ) -> Boolean
*** : (% , NonNegativeInteger) -> %
*** : (% , PositiveInteger) -> %
*** : (% , Integer) -> %

```

These exports come from (p278) `OrderedSet()`:

```

max : (%,% ) -> % if S has ORDSET or S has FINITE

```

```

min : (%,% ) -> % if S has ORDSET or S has FINITE
?>? : (%,% ) -> Boolean if S has ORDSET or S has FINITE
?<=? : (%,% ) -> Boolean if S has ORDSET or S has FINITE
?>=? : (%,% ) -> Boolean if S has ORDSET or S has FINITE

```

=====
StreamAggregate examples
=====

```

A stream aggregate is a linear aggregate which possibly has an infinite number of elements. A basic domain constructor which builds stream aggregates is Stream. From streams, a number of infinite structures such power series can be built. A stream aggregate may also be infinite since it may be cyclic. For example, see DecimalExpansion.

See Also:

- o )show StreamAggregate
  - o )show DecimalExpansion
-

**See:**

- ⇒ “LazyStreamAggregate” (LZSTAGG) 8 on page 699
- ⇐ “LinearAggregate” (LNAGG) 6 on page 467
- ⇐ “UnaryRecursiveAggregate” (URAGG) 6 on page 569

**Exports:**

=====
TriangularSetCategory examples
=====

```

The category of triangular sets of multivariate polynomials with coefficients in an integral domain.

Let  $R$  be an integral domain and  $V$  a finite ordered set of variables,  
 $X_1 < X_2 < \dots < X_n$

A set  $S$  of polynomials in  $R[X_1, X_2, \dots, X_n]$  is triangular if no elements of  $S$  lies in  $R$ , and if two distinct elements of  $S$  have distinct main variables.

Note that the empty set is a triangular set. A triangular set is not necessarily a (lexicographical) Groebner basis and the notion of reduction related to triangular sets is based on the recursive view of polynomials. We recall this notion here. For details see

P. AUBRY, D. LAZARD and M. MORENO MAZA "On the Theories of Triangular Sets" Journal of Symbol. Comp.

A polynomial  $P$  is reduced with respect to a non-constant polynomial  $Q$  if the degree of  $P$  in the main variable of  $Q$  is less than the main degree of  $Q$ . A polynomial  $P$  is reduced with respect to a triangular set  $T$  if it is reduced with respect to every polynomial of  $T$ .

**Attributes Exported:**

- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.
- **finiteAggregate** is true if it is an aggregate with a finite number of elements.

- nil

These are directly exported but not implemented:

```

extendIfCan : (% , P) -> Union(% , "failed")
zeroSetSplit : List P -> List %
zeroSetSplitIntoTriangularSystems :
  List P -> List Record(close: % , open: List P)

```

These are implemented by this category:

```

algebraic? : (V , %) -> Boolean

)abbrev category TSETCAT TriangularSetCategory
++ Author: Marc Moreno Maza (marc@nag.co.uk)
++ Date Created: 04/26/1994
++ Date Last Updated: 12/15/1998
++ References :
++ [1] P. AUBRY, D. LAZARD and M. MORENO MAZA "On the Theories
++      of Triangular Sets" Journal of Symbol. Comp. (to appear)
++ Description:
++ The category of triangular sets of multivariate polynomials
++ with coefficients in an integral domain.
++ Let \axiom{R} be an integral domain and \axiom{V} a finite ordered set of
++ variables, say \axiom{X1 < X2 < ... < Xn}.
++ A set \axiom{S} of polynomials in \axiom{R}[X1,X2,...,Xn] is triangular
++ if no elements of \axiom{S} lies in \axiom{R}, and if two distinct
++ elements of \axiom{S} have distinct main variables.
++ Note that the empty set is a triangular set. A triangular set is not
++ necessarily a (lexicographical) Groebner basis and the notion of
++ reduction related to triangular sets is based on the recursive view
++ of polynomials. We recall this notion here and refer to [1] for more
++ details.
++ A polynomial \axiom{P} is reduced w.r.t a non-constant polynomial
++ \axiom{Q} if the degree of \axiom{P} in the main variable of \axiom{Q}
++ is less than the main degree of \axiom{Q}.
++ A polynomial \axiom{P} is reduced w.r.t a triangular set \axiom{T}
++ if it is reduced w.r.t. every polynomial of \axiom{T}.

```

```

    ++ where \axiom{qs} consists of the polynomials of \axiom{ps}
    ++ satisfying property \axiom{pred?}.
initials : $ -> List P
    ++ \axiom{initials(ts)} returns the list of the non-constant initials
    ++ of the members of \axiom{ts}.
degree : $ -> NonNegativeInteger
    ++ \axiom{degree(ts)} returns the product of main degrees of the
    ++ members of \axiom{ts}.
quasiComponent : $ -> Record(close: List P, open: List P)
    ++ \axiom{quasiComponent(ts)} returns \axiom{[lp, lq]} where \axiom{lp}
    ++ is the list of the members of \axiom{ts} and \axiom{lq} is
    ++ \axiom{initials(ts)}.
normalized? : (P, $) -> Boolean
    ++ \axiom{normalized?(p, ts)} returns true iff \axiom{p} and all
    ++ its iterated initials have degree zero w.r.t. the main variables
    ++ of the polynomials of \axiom{ts}
normalized? : $ -> Boolean
    ++ \axiom{normalized?(ts)} returns true iff for every \axiom{p} in
    ++ \axiom{ts} we have \axiom{normalized?(p, us)} where \axiom{us}
    ++ is \axiom{collectUnder(ts, mvar(p))}.
reduced? : (P, $, ((P, P) -> Boolean)) -> Boolean
    ++ \axiom{reduced?(p, ts, redOp?) } returns true iff \axiom{p} is reduced
    ++ w.r.t. in the sense of the operation \axiom{redOp?}, that is if for
    ++ every \axiom{t} in \axiom{ts} \axiom{redOp?(p, t)} holds.
stronglyReduced? : (P, $) -> Boolean
    ++ \axiom{stronglyReduced?(p, ts)} returns true iff \axiom{p}
    ++ is reduced w.r.t. \axiom{ts}.
headReduced? : (P, $) -> Boolean
    ++ \axiom{headReduced?(p, ts)} returns true iff the head of \axiom{p} is

```

```

++ reduced w.r.t. \axiom{ts}.
initiallyReduced? : (P,$) -> Boolean
++ \axiom{initiallyReduced?(p,ts)} returns true iff \axiom{p} and all
++ its iterated initials are reduced w.r.t. to the elements of
++ \axiom{ts} with the same main variable.
autoReduced? : ($,((P,List(P)) -> Boolean)) -> Boolean
++ \axiom{autoReduced?(ts,redOp?) } returns true iff every element of
++ \axiom{ts} is reduced w.r.t to every other in the sense of
++ \axiom{redOp?}
stronglyReduced? : $ -> Boolean
++ \axiom{stronglyReduced?(ts)} returns true iff every element of
++ \axiom{ts} is reduced w.r.t to any other element of \axiom{ts}.
headReduced? : $ -> Boolean
++ headReduced?(ts) returns true iff the head of every element of
++ \axiom{ts} is reduced w.r.t to any other element of \axiom{ts}.
initiallyReduced? : $ -> Boolean
++ initiallyReduced?(ts) returns true iff for every element \axiom{p}
++ of \axiom{ts}. \axiom{p} and all its iterated initials are reduced
++ w.r.t. to the other elements of \axiom{ts} with the same main
++ variable.
reduce : (P,$,((P,P) -> P),((P,P) -> Boolean) ) -> P
++ \axiom{reduce(p,ts,redOp,redOp?) } returns a polynomial \axiom{r}
++ such that \axiom{redOp?(r,p)} holds for every \axiom{p} of
++ \axiom{ts} and there exists some product \axiom{h} of the initials
++ of the members of \axiom{ts} such that \axiom{h*p - r} lies in the
++ ideal generated by \axiom{ts}. The operation \axiom{redOp} must
++ satisfy the following conditions. For every \axiom{p} and \axiom{q}
++ we have \axiom{redOp?(redOp(p,q),q)} and there exists an integer
++ \axiom{e} and a polynomial \axiom{f} such that
++ \axiom{init(q)^e*p = f*q + redOp(p,q)}.
rewriteSetWithReduction : (List P,$,((P,P) -> P),((P,P) -> Boolean) ) ->
List P
++ \axiom{rewriteSetWithReduction(lp,ts,redOp,redOp?) } returns a list
++ \axiom{lp} of polynomials such that
++ \axiom{[reduce(p,ts,redOp,redOp?) for p in lp]} and \axiom{lp}
++ have the same zeros inside the regular zero set of \axiom{ts}.
++ Moreover, for every polynomial \axiom{q} in \axiom{lp} and every
++ polynomial \axiom{t} in \axiom{ts}
++ \axiom{redOp?(q,t)} holds and there exists a polynomial \axiom{p}
++ in the ideal generated by \axiom{lp} and a product \axiom{h} of
++ \axiom{initials(ts)} such that \axiom{h*p - r} lies in the ideal
++ generated by \axiom{ts}.
++ The operation \axiom{redOp} must satisfy the following conditions.
++ For every \axiom{p} and \axiom{q} we have
++ \axiom{redOp?(redOp(p,q),q)}
++ and there exists an integer \axiom{e} and a polynomial \axiom{f}
++ such that \axiom{init(q)^e*p = f*q + redOp(p,q)}.
stronglyReduce : (P,$) -> P
++ \axiom{stronglyReduce(p,ts)} returns a polynomial \axiom{r} such that
++ \axiom{stronglyReduced?(r,ts)} holds and there exists some product

```

```

++ \axiom{h} of \axiom{initials(ts)}
++ such that \axiom{h*p - r} lies in the ideal generated by \axiom{ts}.
headReduce : (P,$) -> P
++ \axiom{headReduce(p,ts)} returns a polynomial \axiom{r} such that
++ \axiom{headReduce?(r,ts)} holds and there exists some product
++ \axiom{h} of \axiom{initials(ts)} such that \axiom{h*p - r} lies
++ in the ideal generated by \axiom{ts}.
initiallyReduce : (P,$) -> P
++ \axiom{initiallyReduce(p,ts)} returns a polynomial \axiom{r}
++ such that \axiom{initiallyReduced?(r,ts)}
++ holds and there exists some product \axiom{h} of \axiom{initials(ts)}
++ such that \axiom{h*p - r} lies in the ideal generated by \axiom{ts}.
removeZero: (P, $) -> P
++ \axiom{removeZero(p,ts)} returns \axiom{0} if \axiom{p} reduces
++ to \axiom{0} by pseudo-division w.r.t \axiom{ts} otherwise
++ returns a polynomial \axiom{q} computed from \axiom{p}
++ by removing any coefficient in \axiom{p} reducing to \axiom{0}.
collectQuasiMonic: $ -> $
++ \axiom{collectQuasiMonic(ts)} returns the subset of \axiom{ts}
++ consisting of the polynomials with initial in \axiom{R}.
reduceByQuasiMonic: (P, $) -> P
++ \axiom{reduceByQuasiMonic(p,ts)} returns the same as
++ \axiom{remainder(p,collectQuasiMonic(ts)).polnum}.
zeroSetSplit : List P -> List $
++ \axiom{zeroSetSplit(lp)} returns a list \axiom{lts} of triangular
++ sets such that the zero set of \axiom{lp} is the union of the
++ closures of the regular zero sets of the members of \axiom{lts}.
zeroSetSplitIntoTriangularSystems : List P -> _
List Record(close:$,open:List P)
++ \axiom{zeroSetSplitIntoTriangularSystems(lp)} returns a list of
++ triangular systems \axiom{[[ts1,qs1],...,[tsn,qsn]]} such that the
++ zero set of \axiom{lp} is the union of the closures of the
++ \axiom{W_i} where \axiom{W_i} consists of the zeros of \axiom{ts}
++ which do not cancel any polynomial in \axiom{qsi}.
first : $ -> Union(P,"failed")
++ \axiom{first(ts)} returns the polynomial of \axiom{ts} with
++ greatest main variable if \axiom{ts} is not empty, otherwise
++ returns \axiom{"failed"}.
last : $ -> Union(P,"failed")
++ \axiom{last(ts)} returns the polynomial of \axiom{ts} with
++ smallest main variable if \axiom{ts} is not empty, otherwise
++ returns \axiom{"failed"}.
rest : $ -> Union($,"failed")
++ \axiom{rest(ts)} returns the polynomials of \axiom{ts} with smaller
++ main variable than \axiom{mvar(ts)} if \axiom{ts} is not empty,
++ otherwise returns "failed"
algebraicVariables : $ -> List(V)
++ \axiom{algebraicVariables(ts)} returns the decreasingly sorted
++ list of the main variables of the polynomials of \axiom{ts}.
algebraic? : (V,$) -> Boolean

```

```

    ++ \axiom{algebraic?(v,ts)} returns true iff \axiom{v} is the
    ++ main variable of some polynomial in \axiom{ts}.
select : ($,V) -> Union(P,"failed")
    ++ \axiom{select(ts,v)} returns the polynomial of \axiom{ts} with
    ++ \axiom{v} as main variable, if any.
extendIfCan : ($,P) -> Union($,"failed")
    ++ \axiom{extendIfCan(ts,p)} returns a triangular set which encodes
    ++ the simple extension by \axiom{p} of the extension of the base
    ++ field defined by \axiom{ts}, according
    ++ to the properties of triangular sets of the current domain.
    ++ If the required properties do not hold then "failed" is returned.
    ++ This operation encodes in some sense the properties of the
    ++ triangular sets of the current category. Is used to implement
    ++ the \axiom{construct} operation to guarantee that every triangular
    ++ set build from a list of polynomials has the required properties.
extend : ($,P) -> $
    ++ \axiom{extend(ts,p)} returns a triangular set which encodes the
    ++ simple extension by \axiom{p} of the extension of the base field
    ++ defined by \axiom{ts}, according to the properties of triangular
    ++ sets of the current category. If the required properties do not
    ++ hold an error is returned.
if V has Finite
then
    coHeight : $ -> NonNegativeInteger
    ++ \axiom{coHeight(ts)} returns \axiom{size()}\$V minus \axiom{\#ts}.

)abbrev category FDIVCAT FiniteDivisorCategory
++ Category for finite rational divisors on a curve
++ Author: Manuel Bronstein
++ Date Created: 19 May 1993
++ Date Last Updated: 19 May 1993
++ Description:
++ This category describes finite rational divisors on a curve, that
++ is finite formal sums  $\sum(n * P)$  where the n's are integers and the
++ P's are finite rational points on the curve.

FiniteDivisorCategory(F, UP, UPUP, R): Category == Result where
  F   : Field
  UP  : UnivariatePolynomialCategory F
  UPUP: UnivariatePolynomialCategory Fraction UP
  R   : FunctionFieldCategory(F, UP, UPUP)

  ID ==> FractionalIdeal(UP, Fraction UP, UPUP, R)

Result ==> AbelianGroup with
  ideal      : % -> ID
    ++ ideal(D) returns the ideal corresponding to a divisor D.
  divisor    : ID -> %
    ++ divisor(I) makes a divisor D from an ideal I.
  divisor    : R -> %
    ++ divisor(g) returns the divisor of the function g.
  divisor    : (F, F) -> %
    ++ divisor(a, b) makes the divisor  $P: \text{\spad}\{(x = a, y = b)\}$ .
    ++ Error: if P is singular.
  divisor    : (F, F, Integer) -> %
    ++ divisor(a, b, n) makes the divisor
    ++  $\text{\spad}\{nP\}$  where  $P: \text{\spad}\{(x = a, y = b)\}$ .
    ++ P is allowed to be singular if n is a multiple of the rank.
  decompose  : % -> Record(id:ID, principalPart: R)
    ++ decompose(d) returns  $\text{\spad}\{[id, f]\}$  where  $\text{\spad}\{d = (id) + \text{div}(f)\}$ .
  reduce     : % -> %
    ++ reduce(D) converts D to some reduced form (the reduced forms can
    ++ be different in different implementations).
  principal? : % -> Boolean
    ++ principal?(D) tests if the argument is the divisor of a function.
  generator  : % -> Union(R, "failed")
    ++ generator(d) returns f if  $\text{\spad}\{(f) = d\}$ ,
    ++ "failed" if d is not principal.
  divisor    : (R, UP, UP, UP, F) -> %
    ++ divisor(h, d, d', g, r) returns the sum of all the finite points
    ++ where  $\text{\spad}\{h/d\}$  has residue  $\text{\spad}\{r\}$ .
    ++  $\text{\spad}\{h\}$  must be integral.
    ++  $\text{\spad}\{d\}$  must be squarefree.
    ++  $\text{\spad}\{d'\}$  is some derivative of  $\text{\spad}\{d\}$  (not necessarily  $dd/dx$ ).
    ++  $\text{\spad}\{g = \text{gcd}(d, \text{discriminant})\}$  contains the ramified zeros of  $\text{\spad}\{d\}$ 
add

=====
FiniteSetAggregate examples
=====

```

A finite-set aggregate models the notion of a finite set, that is, a collection of elements characterized by membership, but not by order or multiplicity. See Set for an example.

See Also:

- o )show FiniteSetAggregate
- o )show Set

---

See:

⇐ “Dictionary” (DIAGG) 7 on page 594  
⇐ “SetAggregate” (SETAGG) 6 on page 555

**Exports:**

any?	bag	brace	cardinality	coerce
complement	construct	convert	copy	count
dictionary	difference	empty	empty?	eq?
eval	every?	extract!	find	hash
index	insert!	inspect	intersect	latex
less?	lookup	map	map!	max

---

See:

⇒ “TableAggregate” (TBAGG) 9 on page 861  
 ⇐ “Dictionary” (DIAGG) 7 on page 594

**Exports:**

any?	bag	coerce	construct	convert
copy	count	dictionary	empty	empty?
eq?	eval	every?	extract!	find
hash	insert!	inspect	key?	keys
latex	less?	map	map!	member?
members	more?	parts	reduce	remove
remove!	removeDuplicates	sample	search	select
select!	size?	#?	?=?	?~=?

**Attributes exported:**

- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.
- **nil**

**Attributes Used:**

- **finiteAggregate** is true if it is an aggregate with a finite number of elements.

These are directly exported but not implemented:

```
remove! : (Key,%) -> Union(Entry,"failed")
search  : (Key,%) -> Union(Entry,"failed")
```

These are implemented by this category:

```
key? : (Key,%) -> Boolean
member? : (Record(key: Key,entry: Entry),%) -> Boolean
  if Record(key: Key,entry: Entry) has SETCAT
  and $ has finiteAggregate
keys : % -> List Key
```

These exports come from (p594) Dictionary(R)  
 where R=Record(a:SetCategory,b:SetCategory)  
 and S=Record(key: Key,entry: Entry)

```

=====
LazyStreamAggregate examples
=====

```

LazyStreamAggregate is the category of streams with lazy evaluation. It is understood that the function 'empty?' will

cause lazy evaluation if necessary to determine if there are entries. Functions which call 'empty?', e.g. 'first' and 'rest', will also cause lazy evaluation if necessary.

```

)abbrev category LZSTAGG LazyStreamAggregate
++ Author: Clifton J. Williamson
++ Date Created: 22 November 1989
++ Date Last Updated: 20 July 1990
++ Description:
++ LazyStreamAggregate is the category of streams with lazy
++ evaluation. It is understood that the function 'empty?' will
++ cause lazy evaluation if necessary to determine if there are
++ entries. Functions which call 'empty?', for example 'first' and 'rest',
++ will also cause lazy evaluation if necessary.

```

LazyStreamAggregate(S:Type): Category == StreamAggregate(S) with

```

remove: (S -> Boolean,%) -> %
  ++remove(f,st) returns a stream consisting of those elements of stream
  ++ st which do not satisfy the predicate f.
  ++ Note that \spad{remove(f,st) = [x for x in st | not f(x)]}.
  ++
  ++X m:=[i for i in 1..]
  ++X f(i:PositiveInteger):Boolean == even? i
  ++X remove(f,m)

select: (S -> Boolean,%) -> %
  ++select(f,st) returns a stream consisting of those elements of stream
  ++ st satisfying the predicate f.
  ++ Note that \spad{select(f,st) = [x for x in st | f(x)]}.
  ++
  ++X m:=[i for i in 0..]
  ++X select(x->prime? x,m)

explicitEntries?: % -> Boolean
  ++explicitEntries?(s) returns true if the stream s has
  ++ explicitly computed entries, and false otherwise.
  ++
  ++X m:=[i for i in 0..]
  ++X explicitEntries? m

explicitlyEmpty?: % -> Boolean
  ++explicitlyEmpty?(s) returns true if the stream is an
  ++ (explicitly) empty stream.
  ++ Note that this is a null test which will not cause lazy evaluation.
  ++
  ++X m:=[i for i in 0..]
  ++X explicitlyEmpty? m

lazy?: % -> Boolean
  ++lazy?(s) returns true if the first node of the stream s
  ++ is a lazy evaluation mechanism which could produce an
  ++ additional entry to s.
  ++
  ++X m:=[i for i in 0..]
  ++X lazy? m

lazyEvaluate: % -> %
  ++lazyEvaluate(s) causes one lazy evaluation of stream s.
  ++ Caution: the first node must be a lazy evaluation mechanism
  ++ (satisfies \spad{lazy?(s) = true}) as there is no error check.
  ++ Note that a call to this function may
  ++ or may not produce an explicit first entry

```

```

first: % -> S
  ++first(s) returns the first element of stream s.
  ++ Caution: this function should only be called after a \spad{empty?}
  ++ test has been made since there no error check.
  ++
  ++X m:=[i for i in 0..]
  ++X first m

rst: % -> %
  ++rst(s) returns a pointer to the next node of stream s.
  ++ Caution: this function should only be called after a \spad{empty?}
  ++ test has been made since there no error check.
  ++
  ++X m:=[i for i in 0..]
  ++X rst m

numberOfComputedEntries: % -> NonNegativeInteger
  ++numberOfComputedEntries(st) returns the number of explicitly
  ++ computed entries of stream st which exist immediately prior to the
  ++ time this function is called.
  ++
  ++X m:=[i for i in 0..]
  ++X numberOfComputedEntries m

extend: (%,Integer) -> %
  ++extend(st,n) causes entries to be computed, if necessary,
  ++ so that 'st' will have at least 'n' explicit entries or so
  ++ that all entries of 'st' will be computed if 'st' is finite
  ++ with length <= n.
  ++
  ++X m:=[i for i in 0..]
  ++X numberOfComputedEntries m
  ++X extend(m,20)
  ++X numberOfComputedEntries m

complete: % -> %
  ++complete(st) causes all entries of 'st' to be computed.
  ++ this function should only be called on streams which are
  ++ known to be finite.
  ++
  ++X m:=[i for i in 1..]
  ++X n:=filterUntil(i+>i>100,m)
  ++X numberOfComputedEntries n
  ++X complete n
  ++X numberOfComputedEntries n

— ListAggregate.help —

```
=====
ListAggregate examples
=====
```

A list aggregate is a model for a linked list data structure. A linked list is a versatile data structure. Insertion and deletion are efficient and searching is a linear operation.

See Also:

o )show ListAggregate

See:

⇒ “AssociationListAggregate” (ALAGG) [10](#) on page [883](#)

⇐ “ExtensibleLinearAggregate” (ELAGG) [7](#) on page [608](#)

⇐ “FiniteLinearAggregate” (FLAGG) [7](#) on page [616](#)

**Exports:**

any?	children	child?	coerce
concat	concat!	construct	convert
copy	copyInto!	count	cycleEntry
cycleLength	cycleSplit!	cycleTail	cyclic?
delete	delete!	distance	elt
empty	empty?	entries	entry?
eq?	eval	every?	explicitlyFinite?
fill!	find	first	hash
index?	indices	insert	insert!

less?	list	map	map!
max	maxIndex	member?	members
merge	merge!	min	minIndex
more?	new	nodes	node?
parts	position	possiblyInfinite?	qelt
qsetelt!	reduce	remove	remove!
removeDuplicates	removeDuplicates!	rest	reverse
reverse!	sample	second	select
select!	setchildren!	setelt	setfirst!
setlast!	setrest!	setvalue!	size?
sort	sort!	sorted?	split!
swap!	tail	third	value
#?	?.	?..last	?..rest
?..first	?..value	?<?	?<=?
?=?	?>?	?>=?	?~=?

**Attributes exported:**

- **finiteAggregate** is true if it is an aggregate with a finite number of elements.
- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.
- **nil**

These are implemented by this category:

```

copy : % -> %
copyInto! : (%,%,Integer) -> % if $ has shallowlyMutable
delete! : (%,Integer) -> %
delete! : (%,UniversalSegment Integer) -> %
find : ((S -> Boolean),%) -> Union(S,"failed")
insert! : (S,%,Integer) -> %
insert! : (%,%,Integer) -> %
list : S -> %
map : (((S,S) -> S),%,%) -> %
merge : (((S,S) -> Boolean),%,%) -> %

```

```

### MultisetAggregate examples

=====

A multi-set aggregate is a set which keeps track of the multiplicity of its elements.

See Also:

o )show MultisetAggregate

See:

⇒ “OrderedMultisetAggregate” (OMSAGG) 9 on page 827

⇐ “MultiDictionary” (MDAGG) 7 on page 631

⇐ “SetAggregate” (SETAGG) 6 on page 555

**Exports:**

any?	bag	brace	coerce
construct	convert	copy	count
dictionary	difference	duplicates	empty
empty?	eq?	eval	every?
extract!	find	hash	insert!
inspect	intersect	latex	less?
map	map!	member?	members
more?	parts	reduce	remove
remove!	removeDuplicates	removeDuplicates!	sample
select	select!	set	size?
subset?	symmetricDifference	union	#?
?^=?	?<?	?=?	

**Attributes exported:**

- **partiallyOrderedSet** is true if a set with  $<$  which is transitive, but not( $a < b$  or  $a = b$ ) does not necessarily imply  $b < a$ .
- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.
- **nil**

These exports come from (p631) MultiDictionary(S:SetCategory):

```
any? : ((S -> Boolean),%) -> Boolean if $ has finiteAggregate
bag : List S -> %
coerce : % -> OutputForm
```

```

— NonAssociativeRng.help —

=====  
NonAssociativeRng examples  
=====

NonAssociativeRng is a basic ring-type structure, not necessarily commutative or associative, and not necessarily with unit.

Axioms:

$$\begin{aligned}
x*(y+z) &= x*y + x*z \\
(x+y)*z &= x*z + y*z
\end{aligned}$$

Common Additional Axioms

$$\text{noZeroDivisors} \quad ab = 0 \Rightarrow a=0 \text{ or } b=0$$

See Also:

=====
OneDimensionalArrayAggregate examples
=====

```

One-dimensional-array aggregates serves as models for one-dimensional arrays. Categorically, these aggregates are finite linear aggregates with the shallowlyMutable property, that is, any component of the array may be changed without affecting the identity of the overall array. Array data structures are typically represented by a fixed area in storage and cannot efficiently grow or shrink on demand as can list structures (see however FlexibleArray for a data structure which is a cross between a list and an array).

Iteration over, and access to, elements of arrays is extremely fast (and often can be optimized to open-code).

Insertion and deletion however is generally slow since an entirely new

data structure must be created for the result.

?.?	?<?	?<=?	?~=?	?=?
?>?	?>=?			

**Attributes Exported:**

- **finiteAggregate** is true if it is an aggregate with a finite number of elements.
- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.
- **nil**

These are implemented by this category:

```

=====
RegularTriangularSetCategory examples
=====

```

The category of regular triangular sets was introduced under the name

regular chains in M. KALKBRENER "Three contributions to elimination theory".

In P. AUBRY, D. LAZARD and M. MORENO MAZA "On the Theories of Triangular Sets" it is proved that extensions of a field are equivalent notions.

In the following definitions, all polynomials and ideals are taken from the polynomial ring  $k[x_1, \dots, x_n]$  where  $k$  is the fraction field of  $R$ .

The triangular set  $[t_1, \dots, t_m]$  is regular iff for every  $i$  the initial of  $t_{i+1}$  is invertible in the tower of simple extensions associated with  $[t_1, \dots, t_i]$ .

A family  $[T_1, \dots, T_s]$  of regular triangular sets is a split of Kalkbrener of a given ideal  $I$  iff the radical of  $I$  is equal to the intersection of the radical ideals generated by the saturated ideals of the  $[T_1, \dots, T_i]$ .

A family  $[T_1, \dots, T_s]$  of regular triangular sets is a split of Kalkbrener of a given triangular set  $T$  iff it is a split of Kalkbrener of the saturated ideal of  $T$ . Let  $K$  be an algebraic closure of  $k$ .

Assume that  $V$  is finite with cardinality  $n$  and let  $A$  be the affine space  $K^n$ .

For a regular triangular set  $T$  let denote by  $W(T)$  the set of regular zeros of  $T$ . A family  $[T_1, \dots, T_s]$  of regular triangular sets is a split of Lazard of a given subset  $S$  of  $A$  iff the union of the  $W(T_i)$  contains  $S$  and is contained in the closure of  $S$  (w.r.t. Zariski topology).

A family  $[T_1, \dots, T_s]$  of regular triangular sets is a split of Lazard of a given triangular set  $T$  if it is a split of Lazard of  $W(T)$ . Note that if  $[T_1, \dots, T_s]$  is a split of Lazard of  $T$  then it is also a split of Kalkbrener of  $T$ . The converse is false.

This category provides operations related to both kinds of splits, the former being related to ideals decomposition whereas the latter deals with varieties decomposition. See the example illustrating the `RegularTriangularSet` constructor for more explanations about decompositions by means of regular triangular sets.

### Attributes Exported:

- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.
- **finiteAggregate** is true if it is an aggregate with a finite number of elements.
- **nil**

These are directly exported but not implemented:

`augment : (P,%) -> List %`

```

extend : (P,%) -> List %
internalAugment : (P,%) -> %
internalAugment : (List P,%) -> %
intersect : (P,%) -> List %
invertibleElseSplit? : (P,%) -> Union(Boolean,List %)
invertible? : (P,%) -> List Record(val: Boolean,tower: %)
invertible? : (P,%) -> Boolean
invertibleSet : (P,%) -> List %
lastSubResultant : (P,P,%) -> List Record(val: P,tower: %)
lastSubResultantElseSplit : (P,P,%) -> Union(P,List %)
squareFreePart : (P,%) -> List Record(val: P,tower: %)
zeroSetSplit : (List P,Boolean) -> List %

```

These are implemented by this category:

```

algebraicCoefficients? : (P,%) -> Boolean
augment : (P,List %) -> List %
augment : (List P,%) -> List %
augment : (List P,List %) -> List %
extend : (P,List %) -> List %
extend : (List P,%) -> List %

++ Description:
++ The category of regular triangular sets, introduced under
++ the name regular chains in [1] (and other papers).
++ In [3] it is proved that regular triangular sets and towers of simple
++ extensions of a field are equivalent notions.
++ In the following definitions, all polynomials and ideals
++ are taken from the polynomial ring  $\text{spad}\{k[x_1, \dots, x_n]\}$  where  $\text{spad}\{k\}$ 
++ is the fraction field of  $\text{spad}\{R\}$ .
++ The triangular set  $\text{spad}\{[t_1, \dots, t_m]\}$  is regular
++ iff for every  $\text{spad}\{i\}$  the initial of  $\text{spad}\{t_{i+1}\}$  is invertible
++ in the tower of simple extensions associated with  $\text{spad}\{[t_1, \dots, t_i]\}$ .
++ A family  $\text{spad}\{[T_1, \dots, T_s]\}$  of regular triangular sets
++ is a split of Kalkbrener of a given ideal  $\text{spad}\{I\}$ 
++ iff the radical of  $\text{spad}\{I\}$  is equal to the intersection
++ of the radical ideals generated by the saturated ideals
++ of the  $\text{spad}\{[T_1, \dots, T_i]\}$ .
++ A family  $\text{spad}\{[T_1, \dots, T_s]\}$  of regular triangular sets
++ is a split of Kalkbrener of a given triangular set  $\text{spad}\{T\}$ 
++ iff it is a split of Kalkbrener of the saturated ideal of  $\text{spad}\{T\}$ .
++ Let  $\text{spad}\{K\}$  be an algebraic closure of  $\text{spad}\{k\}$ .
++ Assume that  $\text{spad}\{V\}$  is finite with cardinality
++  $\text{spad}\{n\}$  and let  $\text{spad}\{A\}$  be the affine space  $\text{spad}\{K^n\}$ .
++ For a regular triangular set  $\text{spad}\{T\}$  let denote by  $\text{spad}\{W(T)\}$  the
++ set of regular zeros of  $\text{spad}\{T\}$ .
++ A family  $\text{spad}\{[T_1, \dots, T_s]\}$  of regular triangular sets
++ is a split of Lazard of a given subset  $\text{spad}\{S\}$  of  $\text{spad}\{A\}$ 
++ iff the union of the  $\text{spad}\{W(T_i)\}$  contains  $\text{spad}\{S\}$  and
++ is contained in the closure of  $\text{spad}\{S\}$  (w.r.t. Zariski topology).
++ A family  $\text{spad}\{[T_1, \dots, T_s]\}$  of regular triangular sets
++ is a split of Lazard of a given triangular set  $\text{spad}\{T\}$ 
++ if it is a split of Lazard of  $\text{spad}\{W(T)\}$ .
++ Note that if  $\text{spad}\{[T_1, \dots, T_s]\}$  is a split of Lazard of
++  $\text{spad}\{T\}$  then it is also a split of Kalkbrener of  $\text{spad}\{T\}$ .
++ The converse is false.
++ This category provides operations related to both kinds of
++ splits, the former being related to ideals decomposition whereas
++ the latter deals with varieties decomposition.
++ See the example illustrating the RegularTriangularSet constructor for more
++ explanations about decompositions by means of regular triangular sets.

  ++ \spad{invertible?(p,ts)} returns \spad{lbwt} where \spad{lbwt.i}
  ++ is the result of \spad{invertibleElseSplit?(p,lbwt.i.tower)} and
  ++ the list of the \spad{(lqrwt.i).tower} is a split of Kalkbrener of
  ++ \spad{ts}.
invertible?: (P,$) -> Boolean
  ++ \spad{invertible?(p,ts)} returns true iff \spad{p} is invertible
  ++ in the tower associated with \spad{ts}.
invertibleSet: (P,$) -> List $
  ++ \spad{invertibleSet(p,ts)} returns a split of Kalkbrener of the
  ++ quotient ideal of the ideal \axiom{I} by \spad{p} where \spad{I} is
  ++ the radical of saturated of \spad{ts}.
lastSubResultantElseSplit: (P, P, $) -> Union(P,List $)
  ++ \spad{lastSubResultantElseSplit(p1,p2,ts)} returns either
  ++ \spad{g} a quasi-monic gcd of \spad{p1} and \spad{p2} w.r.t.
  ++ the \spad{ts} or a split of Kalkbrener of \spad{ts}.
  ++ This assumes that \spad{p1} and \spad{p2} have the same main
  ++ variable and that this variable is greater than any variable
  ++ occurring in \spad{ts}.
lastSubResultant: (P, P, $) -> List Record(val : P, tower : $)
  ++ \spad{lastSubResultant(p1,p2,ts)} returns \spad{lpwt} such that
  ++ \spad{lpwt.i.val} is a quasi-monic gcd of \spad{p1} and \spad{p2}
  ++ w.r.t. \spad{lpwt.i.tower}, for every \spad{i}, and such
  ++ that the list of the \spad{lpwt.i.tower} is a split of Kalkbrener of

```

```

++ \spad{ts}. Moreover, if \spad{p1} and \spad{p2} do not
++ have a non-trivial gcd w.r.t. \spad{lpwt.i.tower} then
++ \spad{lpwt.i.val} is the resultant of these polynomials w.r.t.
++ \spad{lpwt.i.tower}. This assumes that \spad{p1} and \spad{p2} have
++ the same main variable and that this variable is greater than any
++ variable occurring in \spad{ts}.
squareFreePart: (P,$) -> List Record(val : P, tower : $)
++ \spad{squareFreePart(p,ts)} returns \spad{lpwt} such that
++ \spad{lpwt.i.val} is a square-free polynomial
++ w.r.t. \spad{lpwt.i.tower}, this polynomial being associated with
++ \spad{p} modulo \spad{lpwt.i.tower}, for every \spad{i}. Moreover,
++ the list of the \spad{lpwt.i.tower} is a split
++ of Kalkbrener of \spad{ts}.
++ WARNING: This assumes that \spad{p} is a non-constant polynomial
++ such that if \spad{p} is added to \spad{ts}, then the resulting set
++ is a regular triangular set.
intersect: (P,$) -> List $
++ \spad{intersect(p,ts)} returns the same as
++ \spad{intersect([p],ts)}
intersect: (List P, $) -> List $
++ \spad{intersect(lp,ts)} returns \spad{lts} a split of Lazard
++ of the intersection of the affine variety associated
++ with \spad{lp} and the regular zero set of \spad{ts}.
intersect: (List P, List $) -> List $
++ \spad{intersect(lp,lts)} returns the same as
++ \spad{concat([intersect(lp,ts) for ts in lts])}
intersect: (P, List $) -> List $
++ \spad{intersect(p,lts)} returns the same as
++ \spad{intersect([p],lts)}
augment: (P,$) -> List $
++ \spad{augment(p,ts)} assumes that \spad{p} is a non-constant
++ polynomial whose main variable is greater than any variable
++ of \spad{ts}. This operation assumes also that if \spad{p} is
++ added to \spad{ts} the resulting set, say \spad{ts+p}, is a
++ regular triangular set. Then it returns a split of Kalkbrener
++ of \spad{ts+p}. This may not be \spad{ts+p} itself, if for
++ instance \spad{ts+p} is required to be square-free.
augment: (P,List $) -> List $
++ \spad{augment(p,lts)} returns the same as
++ \spad{concat([augment(p,ts) for ts in lts])}
augment: (List P,$) -> List $
++ \spad{augment(lp,ts)} returns \spad{ts} if \spad{empty? lp},
++ \spad{augment(p,ts)} if \spad{lp = [p]}, otherwise
++ \spad{augment(first lp, augment(rest lp, ts))}
augment: (List P,List $) -> List $
++ \spad{augment(lp,lts)} returns the same as
++ \spad{concat([augment(lp,ts) for ts in lts])}
internalAugment: (P, $) -> $
++ \spad{internalAugment(p,ts)} assumes that \spad{augment(p,ts)}
++ returns a singleton and returns it.

```

```

internalAugment: (List P, $) -> $
  ++ \spad{internalAugment(lp,ts)} returns \spad{ts} if \spad{lp}
  ++ is empty otherwise returns
  ++ \spad{internalAugment(rest lp, internalAugment(first lp, ts))}
extend: (P,$) -> List $
  ++ \spad{extend(p,ts)} assumes that \spad{p} is a non-constant
  ++ polynomial whose main variable is greater than any variable
  ++ of \spad{ts}. Then it returns a split of Kalkbrener
  ++ of \spad{ts+p}. This may not be \spad{ts+p} itself, if for
  ++ instance \spad{ts+p} is not a regular triangular set.
extend: (P, List $) -> List $
  ++ \spad{extend(p,lts)} returns the same as
  ++ \spad{concat([extend(p,ts) for ts in lts])}
extend: (List P,$) -> List $
  ++ \spad{extend(lp,ts)} returns \spad{ts} if \spad{empty? lp}
  ++ \spad{extend(p,ts)} if \spad{lp = [p]} else
  ++ \spad{extend(first lp, extend(rest lp, ts))}
extend: (List P,List $) -> List $
  ++ \spad{extend(lp,lts)} returns the same as
  ++ \spad{concat([extend(lp,ts) for ts in lts])}
zeroSetSplit: (List P, Boolean) -> List $
  ++ \spad{zeroSetSplit(lp,clos?) } returns \spad{lts} a split of
  ++ Kalkbrener of the radical ideal associated with \spad{lp}.
  ++ If \spad{clos?} is false, it is also a decomposition of the
  ++ variety associated with \spad{lp} into the regular zero set of the
  ++ \spad{ts} in \spad{lts} (or, in other words, a split of Lazard of
  ++ this variety). See the example illustrating the
  ++ \spadtype{RegularTriangularSet} constructor for more explanations
  ++ about decompositions by means of regular triangular sets.

=====  
RightModule examples  
=====

The category of right modules over an rng (ring not necessarily with unit). This is an abelian group which supports right multiplication by elements of the rng.

Axioms:

```

x*(a*b) = (x*a)*b
x*(a+b) = (x*a)+(x*b)
(x+y)*x = (x*a)+(y*a)

```

See Also:

o )show RightModule

---

See:

⇒ “BiModule” (BMODULE) 9 on page 790  
⇐ “AbelianGroup” (ABELGRP) 7 on page 582

**Exports:**

```

0          coerce  hash  latex  sample
subtractIfCan  zero?  ?~=?  ?*?  ?+?
?-?          -?     ?=?

```

These are directly exported but not implemented:

```

?*? : (% , R) -> %

```

These exports come from (p582) AbelianGroup():

```

=====
BitAggregate examples
=====

```

The bit aggregate category models aggregates representing large quantities of Boolean data.

See Also:

o )show BitAggregate

---

See:

← “Logic” (LOGIC) 3 on page 153  
 ← “OneDimensionalArrayAggregate” (A1AGG) 8 on page 747  
 ← “OrderedSet” (ORDSET) 4 on page 278

**Exports:**

any?	coerce	concat	construct	convert
copy	copyInto!	count	delete	elt
empty	empty?	entry?	entries	eq?
eval	every?	fill!	find	first
hash	index?	indices	insert	latex
less?	map	map!	max	maxIndex
member?	members	merge	min	minIndex
more?	nand	new	nor	not?
parts	position	qelt	qsetelt!	reduce
remove	removeDuplicates	reverse	reverse!	sample
select	setelt	size?	sort	sort!
sorted?	swap!	xor	#?	?/\?
?<?	?<=?	?=?	?>?	?>=?
?\ /?	^?	?and?	?..?	?or?
~?	?~=?			

**Attributes exported:**

- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.
- **finiteAggregate** is true if it is an aggregate with a finite number of elements.
- **nil**

These are directly exported but not implemented:

```
?and? : (%,% ) -> %
?or?  : (%,% ) -> %
xor   : (%,% ) -> %
```

These are implemented by this category:

```
not?  : % -> %
~?    : % -> %
~?    : % -> %
?/\?  : (%,% ) -> %
? \|/? : (%,% ) -> %
nand  : (%,% ) -> %
nor   : (%,% ) -> %
```

These exports come from (p278) OrderedSet():

```
coerce : % -> OutputForm
hash   : % -> SingleInteger
```

```

latex : % -> String
max : (%,% ) -> %
min : (%,% ) -> %
?=? : (%,% ) -> Boolean
?~=? : (%,% ) -> Boolean
?<? : (%,% ) -> Boolean
?>? : (%,% ) -> Boolean
?<=? : (%,% ) -> Boolean
?>=? : (%,% ) -> Boolean

```

TPDHERE: Note that none of the exports of Logic are needed. Perhaps this can be eliminated.

These exports come from (p747) OneDimensionalArrayAggregate(Boolean):

```

any? : ((Boolean -> Boolean),%) -> Boolean
  if $ has finiteAggregate
concat : (%,% ) -> %
concat : List % -> %
concat : (% , Boolean) -> %
concat : (Boolean , %) -> %

=====
NonAssociativeRing examples
=====

```

A `NonAssociativeRing` is a non associative rng which has a unit, the multiplication is not necessarily commutative or associative.

See Also:

o `)show NonAssociativeRing`

---

See:

← “`MonadWithUnit`” (`MONADWU`) 5 on page 389

← “`NonAssociativeRng`” (`NARNG`) 8 on page 742

**Exports:**

0	1	antiCommutator	associator	characteristic
coerce	commutator	hash	latex	leftPower
leftRecip	one?	recip	rightPower	rightRecip
sample	subtractIfCan	zero?	?*?	?~=?
?**?	?+?	?-?	-?	?=?

These are directly exported but not implemented:

```
characteristic : () -> NonNegativeInteger
```

These are implemented by this category:

```
coerce : Integer -> %
```

These exports come from ([p742](#)) `NonAssociativeRng()`:

```
0 : () -> %
antiCommutator : (%,% ) -> %
associator : (%,%,% ) -> %
coerce : % -> OutputForm
commutator : (%,% ) -> %
hash : % -> SingleInteger
latex : % -> String
leftPower : (% ,PositiveInteger) -> %
rightPower : (% ,PositiveInteger) -> %
sample : () -> %
subtractIfCan : (%,% ) -> Union(%, "failed")
zero? : % -> Boolean
?~=? : (%,% ) -> Boolean
?*? : (PositiveInteger,% ) -> %
?*? : (%,% ) -> %
?+? : (%,% ) -> %
?=? : (%,% ) -> Boolean
```

```

? * ? : (Integer, %) -> %
? * ? : (NonNegativeInteger, %) -> %
? - ? : (% , %) -> %
- ? : % -> %
? * * ? : (% , PositiveInteger) -> %

```

These exports come from (p389) MonadWithUnit():

```

1 : () -> %
leftPower : (% , NonNegativeInteger) -> %
leftRecip : % -> Union(%, "failed")
one? : % -> Boolean
recip : % -> Union(%, "failed")
rightPower : (% , NonNegativeInteger) -> %
rightRecip : % -> Union(%, "failed")
? * * ? : (% , NonNegativeInteger) -> %

=====
NormalizedTriangularSetCategory examples
=====
```

The category of normalized triangular sets. A triangular set `ts` is said normalized if for every algebraic variable `v` of `ts` the polynomial `select(ts,v)` is normalized w.r.t. every polynomial in `collectUnder(ts,v)`.

A polynomial `p` is said normalized w.r.t. a non-constant polynomial `q` if `p` is constant or `degree(p,mdeg(q)) = 0` and `init(p)` is normalized w.r.t. `q`. One of the important features of normalized triangular sets is that they are regular sets.

**Attributes Exported:**

- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.
- **finiteAggregate** is true if it is an aggregate with a finite number of elements.
- **nil**

These exports come from (p763) `RegularTriangularSetCategory(R,E,V,P)` where `R:GcdDomain`, `E:OrderedAbelianMonoidSup`, `V:OrderedSet`, `P:RecursivePolynomialCategory(R,E,V)`:

OrderedAbelianMonoidSup examples
=====

```

This domain is an OrderedAbelianMonoid with a sup operation added. The purpose of the sup operator in this domain is to act as a supremum with respect to the partial order imposed by ‘-’, rather than with respect to the total > order (since that is "max").

Axioms:

```

sup(a,b)-a ~="failed"
sup(a,b)-b ~="failed"
x-a ~="failed" and x-b ~="failed" => x >= sup(a,b)

```

=====
OrderedMultisetAggregate examples
=====

```

An ordered-multiset aggregate is a multiset built over an ordered set  $S$  so that the relative sizes of its entries can be assessed. These aggregates serve as models for priority queues.

See Also:  
o )show OrderedMultisetAggregate

---

**See:**

⇐ “MultisetAggregate” (MSETAGG) 8 on page 736  
⇐ “PriorityQueueAggregate” (PRQAGG) 6 on page 543

**Exports:**

any?	bag	brace	coerce
construct	convert	copy	count
dictionary	difference	empty	empty?
eq?	duplicates	eval	every?
extract!	find	hash	insert!
inspect	intersect	latex	less?
map	map!	max	member?
members	merge	merge!	min
more?	parts	reduce	remove
remove!	removeDuplicates	removeDuplicates!	sample
select	select!	set	size?
subset?	symmetricDifference	union	#?
?<?	?=?	?~?	

**Attributes exported:**

- **partiallyOrderedSet** is true if a set with  $<$  which is transitive, but not( $a < b$  or  $a = b$ ) does not necessarily imply  $b < a$ .
- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.
- **finiteAggregate** is true if it is an aggregate with a finite number of elements.
- **nil**

These are directly exported but not implemented:

```
min : % -> S
```

These exports come from (p736) MultisetAggregate(S:OrderedSet):

```

— Ring.help —

```

=====
Ring examples
=====

```

The category of rings with unity, always associative, but not necessarily commutative.

Rings have two operations, '+' and '\*' and satisfy 5 axioms:

- 1) (associative addition)  $a + (b + c) = (a + b) + c$
- 2) (commutative addition)  $a + b = b + a$
- 3) (associative multiplication)  $a(bc) = (ab)c$
- 4) (distributive multiplication)  $a(b + c) = ab + ac$ ;  $(b + c)a = ba + ca$
- 5) (equation solution)  $a + x = b$  has a solution in R

examples include

- even integers
- integers
- integers module any positive integer
- rational numbers
- real numbers

- complex numbers
- real quaterions
- $a + b\sqrt{2}$  where a and b are rational
- polynomials in real variables with real coefficients
- real continuous functions in a fixed interval
- all power series in a real variable convergent on an interval
- all subsets of an arbitrary set
- all square matrices with elements from a ring

Rings are not necessarily commutative. For example, square 2x2 matices:

$$\begin{array}{cccccc}
 +- & -+ & +- & -+ & +- & -+ \\
 | 0 & 1 & | & 0 & 0 & | = | 1 & 0 & | \\
 | 0 & 0 & | & 1 & 0 & | & | 0 & 0 & | \\
 +- & -+ & +- & -+ & +- & -+ \\
 \\ 
 +- & -+ & +- & -+ & +- & -+ \\
 | 0 & 0 & | & 0 & 1 & | = | 0 & 0 & | \\
 | 1 & 0 & | & 0 & 0 & | & | 0 & 1 & | \\
 +- & -+ & +- & -+ & +- & -+
 \end{array}$$

### Exports:

```

1      0      characteristic  coerce  hash
latex  one?   recip          sample  subtractIfCan
zero?  ?~=?   ?*?          ?**?   ?^?
?+?    ?-?    -?           ?=?

```

### Attributes Exported:

- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has `unitsKnown` means that the operation `recip` can only return “failed” if its argument is not a unit.

These are directly exported but not implemented:

```
characteristic : () -> NonNegativeInteger
```

These are implemented by this category:

```
coerce : Integer -> %
```

These exports come from (p783) `Rng()`:

```

0 : () -> %
coerce : % -> OutputForm
hash : % -> SingleInteger
latex : % -> String
sample : () -> %
subtractIfCan : (%,% ) -> Union(%, "failed")
zero? : % -> Boolean
?+? : (%,% ) -> %
?=? : (%,% ) -> Boolean
?~=? : (%,% ) -> Boolean
?*? : (NonNegativeInteger,% ) -> %
?*? : (PositiveInteger,% ) -> %
?*? : (Integer,% ) -> %
?*? : (%,% ) -> %
?-? : (%,% ) -> %
-? : % -> %
?**? : (% ,PositiveInteger) -> %
?^? : (% ,PositiveInteger) -> %

```

These exports come from (p395) `Monoid()`:

```

1 : () -> %
one? : % -> Boolean
recip : % -> Union(%, "failed")
?**? : (% ,NonNegativeInteger) -> %
?^? : (% ,NonNegativeInteger) -> %

```

## — category RING Ring —

```

)abbrev category RING Ring
++ Description:
++ The category of rings with unity, always associative, but
++ not necessarily commutative.

Ring(): Category == Join(Rng,Monoid,LeftModule(%)) with
characteristic: () -> NonNegativeInteger
  ++ characteristic() returns the characteristic of the ring
  ++ this is the smallest positive integer n such that
  ++ \spad{n*x=0} for all x in the ring, or zero if no such n
  ++ exists.
  --We can not make this a constant, since some domains are mutable
coerce: Integer -> %
  ++ coerce(i) converts the integer i to a member of the given domain.
-- recip: % -> Union(%, "failed") -- inherited from Monoid
unitsKnown
  ++ recip truly yields
  ++ reciprocal or "failed" if not a unit.
  ++ Note that \spad{recip(0) = "failed"}.
add
n:Integer
coerce(n) == n * 1$%

```

=====
SquareFreeRegularTriangularSetCategory examples
=====

```

The category of square-free regular triangular sets. A regular triangular set `ts` is square-free if the gcd of any polynomial `p` in `ts` and `differentiate(p,mvar(p))` w.r.t. `collectUnder(ts,mvar(p))` has degree zero w.r.t. `mvar(p)`. Thus any square-free regular set defines a tower of square-free simple extensions.

**Attributes Exported:**

- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.
- **finiteAggregate** is true if it is an aggregate with a finite number of elements.
- **nil**

```

=====
StringAggregate examples
=====

```

A string aggregate is a category for strings, that is, one dimensional arrays of characters.

See Also:

- o )show StringAggregate

---

See:

⇒ “StringCategory” (STRICAT) [10](#) on page [982](#)

⇐ “OneDimensionalArrayAggregate” (A1AGG) [8](#) on page [747](#)

**Exports:**

any?	coerce	concat	construct	copy
convert	copyInto!	count	delete	elt
empty	empty?	entries	entry?	eval
every?	eq?	fill!	find	first
hash	index?	indices	insert	latex
leftTrim	less?	lowerCase	lowerCase!	map
map!	match	match?	max	maxIndex
member?	members	merge	min	minIndex
more?	new	parts	position	prefix?
qelt	qsetelt!	reduce	remove	removeDuplicates
replace	reverse	reverse!	rightTrim	sample
setelt	size?	sort	sort!	sorted?
split	substring?	suffix?	swap!	trim
upperCase	upperCase!	#?	?~=?	?..?
?<?	?<=?	?=?	?>?	?>=?

**Attributes exported:**

- **finiteAggregate** is true if it is an aggregate with a finite number of elements.
- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.
- **nil**

These are directly exported but not implemented:

```

leftTrim : (% ,Character) -> %
leftTrim : (% ,CharacterClass) -> %
lowerCase! : % -> %
match : (% ,% ,Character) -> NonNegativeInteger
match? : (% ,% ,Character) -> Boolean
position : (CharacterClass ,% ,Integer) -> Integer
position : (% ,% ,Integer) -> Integer
replace : (% ,UniversalSegment Integer ,%) -> %
rightTrim : (% ,Character) -> %
rightTrim : (% ,CharacterClass) -> %
split : (% ,Character) -> List %
split : (% ,CharacterClass) -> List %
substring? : (% ,% ,Integer) -> Boolean
suffix? : (% ,% ) -> Boolean
upperCase! : % -> %

```

These are implemented by this category:

```

coerce : Character -> %
lowerCase : % -> %
prefix? : (% ,% ) -> Boolean

```

```

trim : (% ,CharacterClass) -> %
trim : (% ,Character) -> %
upperCase : % -> %
?.? : (% ,%) -> %

```

These exports come from (p747) OneDimensionalArrayAggregate(Character):

```

any? : ((Character -> Boolean),%) -> Boolean
      if $ has finiteAggregate
coerce : % -> OutputForm if Character has SETCAT

```

— category SRAGG StringAggregate —

```

)abbrev category SRAGG StringAggregate
++ Author: Stephen Watt and Michael Monagan.
++ revised by Manuel Bronstein and Richard Jenks
++ Date Created: August 87 through August 88
++ Date Last Updated: April 1991
++ Description:
++ A string aggregate is a category for strings, that is,
++ one dimensional arrays of characters.

```

```

StringAggregate: Category == OneDimensionalArrayAggregate Character with
lowerCase      : % -> %

```

```

++ lowerCase(s) returns the string with all characters in lower case.
lowerCase_!: % -> %
++ lowerCase!(s) destructively replaces the alphabetic characters
++ in s by lower case.
upperCase      : % -> %
++ upperCase(s) returns the string with all characters in upper case.
upperCase_!: % -> %
++ upperCase!(s) destructively replaces the alphabetic characters
++ in s by upper case characters.
prefix?        : (% , %) -> Boolean
++ prefix?(s,t) tests if the string s is the initial substring of t.
++ Note that \axiom{prefix?(s,t) ==
++   reduce(and,[s.i = t.i for i in 0..maxIndex s])}.
suffix?        : (% , %) -> Boolean
++ suffix?(s,t) tests if the string s is the final substring of t.
++ Note that \axiom{suffix?(s,t) ==
++   reduce(and,[s.i = t.(n - m + i) for i in 0..maxIndex s])}
++ where m and n denote the maxIndex of s and t respectively.
substring?: (% , % , Integer) -> Boolean
++ substring?(s,t,i) tests if s is a substring of t beginning at
++ index i.
++ Note that \axiom{substring?(s,t,0) = prefix?(s,t)}.
match: (% , % , Character) -> NonNegativeInteger
++ match(p,s,wc) tests if pattern \axiom{p} matches subject \axiom{s}
++ where \axiom{wc} is a wild card character. If no match occurs,
++ the index \axiom{0} is returned; otherwise, the value returned
++ is the first index of the first character in the subject matching
++ the subject (excluding that matched by an initial wild-card).
++ For example, \axiom{match("to*", "yorktown", "*")} returns \axiom{5}
++ indicating a successful match starting at index \axiom{5} of
++ \axiom{"yorktown"}.
match?: (% , % , Character) -> Boolean
++ match?(s,t,c) tests if s matches t except perhaps for
++ multiple and consecutive occurrences of character c.
++ Typically c is the blank character.
replace        : (% , UniversalSegment(Integer), %) -> %
++ replace(s,i..j,t) replaces the substring \axiom{s(i..j)}
++ of s by string t.
position       : (% , % , Integer) -> Integer
++ position(s,t,i) returns the position j of the substring s in
++ string t, where \axiom{j >= i} is required.
position       : (CharacterClass, % , Integer) -> Integer
++ position(cc,t,i) returns the position \axiom{j >= i} in t of
++ the first character belonging to cc.
coerce        : Character -> %
++ coerce(c) returns c as a string s with the character c.
split: (% , Character) -> List %
++ split(s,c) returns a list of substrings delimited by character c.
split: (% , CharacterClass) -> List %
++ split(s,cc) returns a list of substrings delimited by

```

```

    ++ characters in cc.
trim: (% , Character) -> %
    ++ trim(s,c) returns s with all characters c deleted from right
    ++ and left ends.
    ++ For example, \axiom{trim(" abc ", char " ")} returns \axiom{"abc"}.
trim: (% , CharacterClass) -> %
    ++ trim(s,cc) returns s with all characters in cc deleted from right
    ++ and left ends.
    ++ For example, \axiom{trim("(abc)", charClass "()")}
    ++ returns \axiom{"abc"}.
leftTrim: (% , Character) -> %
    ++ leftTrim(s,c) returns s with all leading characters c deleted.
    ++ For example, \axiom{leftTrim(" abc ", char " ")}
    ++ returns \axiom{"abc "}.
leftTrim: (% , CharacterClass) -> %
    ++ leftTrim(s,cc) returns s with all leading characters in cc deleted.
    ++ For example, \axiom{leftTrim("(abc)", charClass "()")}
    ++ returns \axiom{"abc"}.
rightTrim: (% , Character) -> %
    ++ rightTrim(s,c) returns s with all trailing occurrences of c deleted.
    ++ For example, \axiom{rightTrim(" abc ", char " ")}
    ++ returns \axiom{" abc"}.
rightTrim: (% , CharacterClass) -> %
    ++ rightTrim(s,cc) returns s with all trailing occurrences of
    ++ characters in cc deleted.
    ++ For example, \axiom{rightTrim("(abc)", charClass "()")}
    ++ returns \axiom{"(abc)".
elt: (% , %) -> %
    ++ elt(s,t) returns the concatenation of s and t. It is provided to
    ++ allow juxtaposition of strings to work as concatenation.
    ++ For example, \axiom{"smoo" "shed"} returns \axiom{"smooshed"}.
add
trim(s: % , c: Character) == leftTrim(rightTrim(s, c), c)
trim(s: % , cc: CharacterClass) == leftTrim(rightTrim(s, cc), cc)

```
=====
VectorCategory examples
=====
```

VectorCategory represents the type of vector like objects, i.e. finite sequences indexed by some finite segment of the integers. The operations available on vectors depend on the structure of the underlying components. Many operations from the component domain are defined for vectors componentwise. It can be assumed that extraction or updating components can be done in constant time.

#?	?*?	?+?	?-?	?<?
?<=?	?=?	?>?	?>=?	-?
?.	?~=?			

**Attributes Exported:**

- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.
- **finiteAggregate** is true if it is an aggregate with a finite number of elements.

These are implemented by this category:

```

cross : (%,%) -> % if R has RING
dot : (%,%) -> R if R has RING
length : % -> R if R has RING and R has RADCAT
magnitude : % -> R if R has RING and R has RADCAT
outerProduct : (%,%) -> Matrix R if R has RING
zero : NonNegativeInteger -> % if R has ABELMON

=====
AssociationListAggregate examples
=====

```

An association list is a list of key entry pairs which may be viewed as a table. It is a poor mans version of a table; searching for a key is a linear operation.

See Also:

o )show AssociationListAggregate

**Attributes exported:**

- **shallowlyMutable** is true if its values have immediate components that are updateable (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.

- **finiteAggregate** is true if it is an aggregate with a finite number of elements.
- **nil**

These are directly exported but not implemented:

```
assoc : (Key,%) -> Union(Record(key: Key,entry: Entry),"failed")
```

These exports come from (p861) TableAggregate(Key, Entry)  
 where Key:SetCategory and Entry:SetCategory

— category ALAGG AssociationListAggregate —

```
)abbrev category ALAGG AssociationListAggregate
++ Author: Michael Monagan; revised by Manuel Bronstein and Richard Jenks
++ Date Created: August 87 through August 88
++ Date Last Updated: April 1991
++ Description:
++ An association list is a list of key entry pairs which may be viewed
++ as a table. It is a poor mans version of a table:
++ searching for a key is a linear operation.
```

```
AssociationListAggregate(Key:SetCategory,Entry:SetCategory): Category ==
  Join(TableAggregate(Key, Entry), _
    ListAggregate Record(key:Key,entry:Entry)) with
  assoc: (Key, %) -> Union(Record(key:Key,entry:Entry), "failed")
  ++ assoc(k,u) returns the element x in association list u stored
  ++ with key k, or "failed" if u has no key k.
```

### Exports:

1	0	coerce	hash	latex
one?	recip	sample	zero?	characteristic
charthRoot	subtractIfCan	?~=?	?^?	?*?
?**?	?+?	?-?	-?	?=?

### Attributes exported:

- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation `recip` can only return “failed” if its argument is not a unit.

These are directly exported but not implemented:

```
charthRoot : % -> Union(%, "failed")
```

These exports come from (p834) `Ring()`:

```
0 : () -> %
1 : () -> %
characteristic : () -> NonNegativeInteger
coerce : Integer -> %
coerce : % -> OutputForm
hash : % -> SingleInteger
latex : % -> String
one? : % -> Boolean
recip : % -> Union(%, "failed")

=====
CommutativeRing examples
=====

```

The category of commutative rings with unity, i.e. rings where \* is

commutative, and which have a multiplicative identity element.

See Also:

o )show CommutativeRing

---

Commutative Rings are a subset of IntegralDomains.

⇒ “IntegralDomain” (INTDOM) 12 on page 1107.

See:

⇒ “ComplexCategory” (COMPCAT) 20 on page 1685

⇒ “IntegralDomain” (INTDOM) 12 on page 1107

⇒ “FunctionSpace” (FS) 17 on page 1400

⇒ “MonogenicAlgebra” (MONOGEN) 19 on page 1665

⇒ “RealClosedField” (RCFIELD) 17 on page 1454

⇒ “UnivariatePolynomialCategory” (UPOLYC) 17 on page 1535

⇐ “BiModule” (BMODULE) 9 on page 790

⇐ “Ring” (RING) 9 on page 834

Exports:

1	0	coerce	hash	latex
one?	recip	sample	zero?	characteristic
subtractIfCan	?~=?	?^?	?*?	?**?
?+?	?-?	-?	?=?	

Attributes exported:

- **commutative**(“\*”) is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all x.
- **rightUnitary** is true if  $x * 1 = x$  for all x.

These exports come from (p834) Ring():

```
0 : () -> %
1 : () -> %
characteristic : () -> NonNegativeInteger
coerce : Integer -> %
coerce : % -> OutputForm
hash : % -> SingleInteger
latex : % -> String

=====
DifferentialRing examples
=====

```

An ordinary differential ring, that is, a ring with an operation differentiate.

Axioms:

```

differentiate(x+y) = differentiate(x)+differentiate(y)
differentiate(x*y) = x*differentiate(y) + differentiate(x)*y

```

See Also:

```

o )show DifferentialRing

```

---

See:

⇒ “IntegerNumberSystem” (INS) [16](#) on page [1290](#)  
 ⇒ “FiniteFieldCategory” (FFIELDC) [18](#) on page [1584](#)  
 ⇒ “UnivariatePolynomialCategory” (UPOLYC) [17](#) on page [1535](#)  
 ⇐ “Ring” (RING) [9](#) on page [834](#)

**Exports:**

```

1          0          characteristic  coerce  D
differentiate  hash          latex          one?    recip
sample        subtractIfCan  zero?          ?~=?   ?**?
?^?          ??          ?+?          ?-?    -?
?=?
```

**Attributes exported:**

- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation `recip` can only return “failed” if its argument is not a unit.

These are directly exported but not implemented:

```
differentiate : % -> %
```

These are implemented by this category:

```

D : % -> %
D : (% , NonNegativeInteger) -> %
differentiate : (% , NonNegativeInteger) -> %
```

These exports come from ([p834](#)) `Ring()`:

```

0 : () -> %
1 : () -> %
characteristic : () -> NonNegativeInteger
coerce : Integer -> %
coerce : % -> OutputForm
hash : % -> SingleInteger
latex : % -> String
one? : % -> Boolean
recip : % -> Union(%, "failed")
sample : () -> %
subtractIfCan : (% , %) -> Union(%, "failed")
zero? : % -> Boolean
?~=? : (% , %) -> Boolean
?**? : (% , NonNegativeInteger) -> %
?**? : (% , PositiveInteger) -> %
?^? : (% , NonNegativeInteger) -> %
?^? : (% , PositiveInteger) -> %
?? : (% , %) -> %
```

```

???: (NonNegativeInteger,%) -> %
???: (Integer,%) -> %
???: (PositiveInteger,%) -> %
?+?: (%,%) -> %
?-?: (%,%) -> %
-?: % -> %
?=? : (%,%) -> Boolean

```

=====
LeftAlgebra examples
=====

```

The category of all left algebras over an arbitrary ring.

See Also:

o )show LeftAlgebra

---

See:

⇐ “LeftModule” (LMODULE) 8 on page 718

⇐ “Ring” (RING) 9 on page 834

**Exports:**

0	1	coerce	hash	latex
one?	recip	sample	zero?	characteristic
subtractIfCan	?*?	?+?	?-?	-?
?=?	?~=?	?**?	?^?	

**Attributes Exported:**

- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation `recip` can only return “failed” if its argument is not a unit.

These are implemented by this category:

```
coerce : R -> %
```

These exports come from (p834) `Ring()`:

```
0 : () -> %
1 : () -> %
characteristic : () -> NonNegativeInteger
coerce : % -> OutputForm
coerce : Integer -> %
hash : % -> SingleInteger
latex : % -> String
one? : % -> Boolean
recip : % -> Union(%, "failed")
sample : () -> %
subtractIfCan : (%,% ) -> Union(%, "failed")
zero? : % -> Boolean
?+? : (%,% ) -> %
?=? : (%,% ) -> Boolean
?~=? : (%,% ) -> Boolean
?**? : (NonNegativeInteger,% ) -> %
?**? : (PositiveInteger,% ) -> %
?**? : (Integer,% ) -> %
?**? : (%,% ) -> %
?-? : (%,% ) -> %
-? : % -> %
?***? : (% , PositiveInteger) -> %
?***? : (% , NonNegativeInteger) -> %
?^? : (% , NonNegativeInteger) -> %
?^? : (% , PositiveInteger) -> %
```

These exports come from (p718) `LeftModule(R:Type)`:

```
?**? : (R,% ) -> %
```

```

)abbrev category LALG LeftAlgebra
++ Author: Larry A. Lambe

```

=====
PartialDifferentialRing examples
=====

```

A partial differential ring with differentiations indexed by a parameter type S.

Axioms:

```

differentiate(x+y,e)=differentiate(x,e)+differentiate(y,e)
differentiate(x*y,e)=x*differentiate(y,e)+differentiate(x,e)*y

```

See Also:

o )show PartialDifferentialRing

See:

⇒ “DifferentialExtension” (DIFEXT) [11](#) on page [1015](#)

⇒ “FunctionSpace” (FS) [17](#) on page [1400](#)

⇒ “MultivariateTaylorSeriesCategory” (MTSCAT) [15](#) on page [1255](#)

⇒ “PolynomialCategory” (POLYCAT) [16](#) on page [1317](#)

⇐ “Ring” (RING) [9](#) on page [834](#)

**Exports:**

1	0	characteristic	coerce	D
differentiate	hash	latex	one?	recip
sample	subtractIfCan	zero?	?^?	?*?
?~=?	?**?	?+?	?-?	-?
?=?				

**Attributes exported:**

- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation `recip` can only return “failed” if its argument is not a unit.

These are directly exported but not implemented:

```
differentiate : (% , S) -> %
```

These are implemented by this category:

```
D : (% , S) -> %
D : (% , List S) -> %
D : (% , S , NonNegativeInteger) -> %
D : (% , List S , List NonNegativeInteger) -> %
differentiate : (% , List S) -> %
differentiate : (% , S , NonNegativeInteger) -> %
differentiate : (% , List S , List NonNegativeInteger) -> %
```

These exports come from ([p834](#)) `Ring()`:

```
0 : () -> %
1 : () -> %
characteristic : () -> NonNegativeInteger
coerce : Integer -> %
coerce : % -> OutputForm
```

```

hash : % -> SingleInteger
latex : % -> String
one? : % -> Boolean
recip : % -> Union(%, "failed")
sample : () -> %
subtractIfCan : (%,%) -> Union(%, "failed")
zero? : % -> Boolean
?+? : (%,%) -> %
?=? : (%,%) -> Boolean
?~=? : (%,%) -> Boolean
?*? : (%,%) -> %
?*? : (Integer,%) -> %
?*? : (PositiveInteger,%) -> %
?*? : (NonNegativeInteger,%) -> %
?-? : (%,%) -> %
-? : % -> %
?^? : (%,PositiveInteger) -> %
?^? : (%,NonNegativeInteger) -> %
?***? : (%,NonNegativeInteger) -> %
?***? : (%,PositiveInteger) -> %

```

## RectangularMatrixCategory (RMATCAT)

We define three categories for matrices

- MatrixCategory is the category of all matrices
- RectangularMatrixCategory is the category of all matrices of a given dimension
- SquareMatrixCategory inherits from RectangularMatrixCategory

RectangularMatrixCategory does not automatically inherit MatrixCategory. Note that domains in DirectProductCategory( $n,R$ ), which are expected as parameters of RectangularMatrixCategory do not satisfy FiniteLinearAggregate( $R$ ) as required in MatrixCategory.

The RectangularMatrix domain is matrices of fixed dimension.

— category R<sub>MATCAT</sub> RectangularMatrixCategory —

```

)abbrev category RMATCAT RectangularMatrixCategory
++ Authors: Grabmeier, Gschnitzer, Williamson
++ Date Created: 1987
++ Date Last Updated: July 1990
++ Description:
++ \spadtype{RectangularMatrixCategory} is a category of matrices of fixed
++ dimensions. The dimensions of the matrix will be parameters of the
++ domain. Domains in this category will be R-modules and will be non-mutable.

RectangularMatrixCategory(m,n,R,Row,Col): Category == Definition where
  m,n : NonNegativeInteger
  R : Ring
  Row : DirectProductCategory(n,R)
  Col : DirectProductCategory(m,R)

Definition ==> Join(BiModule(R,R),HomogeneousAggregate(R)) with

  finiteAggregate
  ++ matrices are finite

  if R has CommutativeRing then Module(R)

--% Matrix creation

matrix: List List R -> %
  ++ \spad{matrix(l)} converts the list of lists l to a matrix, where the

```

```

    ++ list of lists is viewed as a list of the rows of the matrix.

--% Predicates

square? : % -> Boolean
    ++ \spad{square?(m)} returns true if m is a square matrix (that is, if m
    ++ has the same number of rows as columns) and false otherwise.

diagonal?: % -> Boolean
    ++ \spad{diagonal?(m)} returns true if the matrix m is square and
    ++ diagonal (that is, all entries of m not on the diagonal are zero) and
    ++ false otherwise.

symmetric?: % -> Boolean
    ++ \spad{symmetric?(m)} returns true if the matrix m is square and
    ++ symmetric (that is, \spad{m[i,j] = m[j,i]} for all \spad{i} and j) and
    ++ false otherwise.

antisymmetric?: % -> Boolean
    ++ \spad{antisymmetric?(m)} returns true if the matrix m is square and
    ++ antisymmetric. That is,
    ++ \spad{m[i,j] = -m[j,i]} for all \spad{i} and j
    ++ and false otherwise.

--% Size inquiries

minRowIndex : % -> Integer
    ++ \spad{minRowIndex(m)} returns the index of the 'first' row of the
    ++ matrix m.

maxRowIndex : % -> Integer
    ++ \spad{maxRowIndex(m)} returns the index of the 'last' row of the
    ++ matrix m.

minColIndex : % -> Integer
    ++ \spad{minColIndex(m)} returns the index of the 'first' column of the
    ++ matrix m.

maxColIndex : % -> Integer
    ++ \spad{maxColIndex(m)} returns the index of the 'last' column of the
    ++ matrix m.

nrows : % -> NonNegativeInteger
    ++ \spad{nrows(m)} returns the number of rows in the matrix m.

ncols : % -> NonNegativeInteger
    ++ \spad{ncols(m)} returns the number of columns in the matrix m.

--% Part extractions

```

```

listOfLists: % -> List List R
  ++ \spad{listOfLists(m)} returns the rows of the matrix m as a list
  ++ of lists.

elt: (%,Integer,Integer) -> R
  ++ \spad{elt(m,i,j)} returns the element in the \spad{i}th row and
  ++ \spad{j}th column of the matrix m.
  ++ Error: if indices are outside the proper
  ++ ranges.

qelt: (%,Integer,Integer) -> R
  ++ \spad{qelt(m,i,j)} returns the element in the \spad{i}th row and
  ++ \spad{j}th column of
  ++ the matrix m. Note that there is NO error check to determine
  ++ if indices are in the proper ranges.

elt: (%,Integer,Integer,R) -> R
  ++ \spad{elt(m,i,j,r)} returns the element in the \spad{i}th row and
  ++ \spad{j}th column of the matrix m, if m has an \spad{i}th row and a
  ++ \spad{j}th column, and returns r otherwise.

row: (%,Integer) -> Row
  ++ \spad{row(m,i)} returns the \spad{i}th row of the matrix m.
  ++ Error: if the index is outside the proper range.

column: (%,Integer) -> Col
  ++ \spad{column(m,j)} returns the \spad{j}th column of the matrix m.
  ++ Error: if the index outside the proper range.

--% Map and Zip

map: (R -> R,% ) -> %
  ++ \spad{map(f,a)} returns b, where \spad{b(i,j) = a(i,j)} for all i, j.

map:((R,R) -> R,%,% ) -> %
  ++ \spad{map(f,a,b)} returns c, where c is such that
  ++ \spad{c(i,j) = f(a(i,j),b(i,j))} for all \spad{i}, j.

--% Arithmetic

if R has IntegralDomain then

  "exquo": (% ,R) -> Union(%,"failed")
    ++ \spad{exquo(m,r)} computes the exact quotient of the elements
    ++ of m by r, returning \axiom{"failed"} if this is not possible.

if R has Field then

  "/": (% ,R) -> %
    ++ \spad{m/r} divides the elements of m by r. Error: if \spad{r = 0}.

```

```

--% Linear algebra

if R has EuclideanDomain then

  rowEchelon: % -> %
  ++ \spad{rowEchelon(m)} returns the row echelon form of the matrix m.

if R has IntegralDomain then

  rank: % -> NonNegativeInteger
  ++ \spad{rank(m)} returns the rank of the matrix m.

  nullity: % -> NonNegativeInteger
  ++ \spad{nullity(m)} returns the nullity of the matrix m. This is
  ++ the dimension of the null space of the matrix m.

  nullSpace: % -> List Col
  ++ \spad{nullSpace(m)} returns a basis for the null space of
  ++ the matrix m.

=====  
SquareFreeNormalizedTriangularSetCategory examples

=====

The category of square-free and normalized triangular sets.  
Thus, up to the primitivity axiom of D. LAZARD  
"A new method for solving algebraic systems of positive dimension",  
these sets are Lazard triangular sets.

#?	?<?	?<=?	?>?	?>=?
?=?	?..?	?~=?		

**Attributes exported:**

- **shallowlyMutable** is true if its values have immediate components that are update-able (mutable). Note that the properties of any component domain are irrelevant to the shallowlyMutable proper.
- **finiteAggregate** is true if it is an aggregate with a finite number of elements.
- **nil**

These are directly exported but not implemented:

```
string : Integer -> %
```

These exports come from (p850) StringAggregate():

=====
UnivariateSkewPolynomialCategory examples
=====
```

This is the category of univariate skew polynomials over an Ore coefficient ring. The multiplication is given by

$$x a = \sigma(a) x + \delta a$$

This category is an evolution of the types `MonogenicLinearOperator`, `OppositeMonogenicLinearOperator`, and `NonCommutativeOperatorDivision`

See Also:

## ===== Algebra examples =====

The category of associative algebras (modules which are themselves rings).

**Axioms:**

```

(b+c)::% = (b::%) + (c::%)
(b*c)::% = (b::%) * (c::%)
(1::R)::% = 1::%
b*x = (b::%)*x
r*(a*b) = (r*a)*b = a*(r*b)

```

**See Also:**

o )show Algebra

**See:**

⇒ “DivisionRing” (DIVRING) [12](#) on page [1073](#)  
⇒ “FiniteRankAlgebra” (FINRALG) [17](#) on page [1393](#)  
⇒ “FunctionSpace” (FS) [17](#) on page [1400](#)  
⇒ “IntegralDomain” (INTDOM) [12](#) on page [1107](#)

⇐ “Module” (MODULE) [10](#) on page [938](#)  
⇐ “Ring” (RING) [9](#) on page [834](#)

**Exports:**

1	0	characteristic	coerce	hash
latex	one?	recip	sample	subtractIfCan
zero?	?*?	?+?	?-?	-?
?=?	?~=?	?**?	?^?	

**Attributes exported:**

- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .

These are implemented by this category:

```
coerce : R -> %
```

These exports come from (p[834](#)) `Ring()`:

```

0 : () -> %
1 : () -> %
characteristic : () -> NonNegativeInteger
coerce : Integer -> %
coerce : % -> OutputForm
hash : % -> SingleInteger
latex : % -> String
one? : % -> Boolean
recip : % -> Union(%, "failed")
sample : () -> %
subtractIfCan : (%,% ) -> Union(%, "failed")
zero? : % -> Boolean
?+? : (%,% ) -> %
?=? : (%,% ) -> Boolean
?~=? : (%,% ) -> Boolean
???: (NonNegativeInteger,% ) -> %
???: (PositiveInteger,% ) -> %
???: (Integer,% ) -> %
???: (%,% ) -> %

**Exports:**

1	0	characteristic	coerce	D
differentiate	hash	latex	one?	recip
sample	subtractIfCan	zero?	?*?	?~=?
?**?	?+?	?-?	-?	?=?
?^?				

**Attributes exported:**

- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation `recip` can only return “failed” if its argument is not a unit.

These are directly exported but not implemented:

```
differentiate : (%,(R -> R)) -> %
```

These are implemented by this category:

```
D : (%,(R -> R)) -> %
D : (%,(R -> R),NonNegativeInteger) -> %
differentiate : % -> % if R has DIFRING
differentiate : (%,(R -> R),NonNegativeInteger) -> %
differentiate : (%,Symbol) -> % if R has PDRING SYMBOL
```

These exports come from (p834) Ring():

```
0 : () -> %
1 : () -> %
```

```

characteristic : () -> NonNegativeInteger
coerce : Integer -> %
coerce : % -> OutputForm
hash : % -> SingleInteger
latex : % -> String

=====
LinearOrdinaryDifferentialOperatorCategory examples
=====
```

LinearOrdinaryDifferentialOperatorCategory is the category of differential operators with coefficients in a ring A with a given derivation.

Multiplication of operators corresponds to functional composition:

$$(L1 * L2).(f) = L1 L2 f$$

See Also:

o )show LinearOrdinaryDifferentialOperatorCategory

\_\_\_\_\_

**See:**

⇐ “Eltable” (ELTAB) [2](#) on page [52](#)

⇐ “UnivariateSkewPolynomialCategory” (OREPCAT) [10](#) on page [992](#)

**Exports:**

0	1	adjoint
apply	characteristic	coefficient
coefficients	coerce	content
D	degree	directSum
exquo	hash	latex
leadingCoefficient	leftDivide	leftExactQuotient
leftExtendedGcd	leftGcd	leftLcm
leftQuotient	leftRemainder	minimumDegree
monicLeftDivide	monicRightDivide	monomial
one?	primitivePart	recip
reductum	retract	retractIfCan
rightDivide	rightExactQuotient	rightExtendedGcd
rightGcd	rightLcm	rightQuotient
rightRemainder	sample	subtractIfCan
symmetricPower	symmetricProduct	symmetricSquare
zero?	?^?	?..?
?~=?	?*?	?**?
?+?	?-?	-?
?=?		

**Attributes Exported:**

- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has `unitsKnown` means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .

These are directly exported but not implemented:

```

Vector Spaces (not necessarily finite dimensional) over a field.

See Also:

o )show VectorSpace

---

**See:**

⇒ “ExtensionField” (XF) [18](#) on page [1576](#)

⇐ “Module” (MODULE) [10](#) on page [938](#)

**Exports:**

0	coerce	dimension	hash	latex
sample	subtractIfCan	zero?	?~=?	?*?
?+?	?-?	-?	?/?	?=?

**Attributes exported:**

- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .

These are directly exported but not implemented:

```
dimension : () -> CardinalNumber
```

These are implemented by this category:

```
?/? : (% , S) -> %
```

These exports come from ([p938](#)) Module():

```
?*? : (% , S) -> %
0 : () -> %
coerce : % -> OutputForm
hash : % -> SingleInteger
latex : % -> String
sample : () -> %
subtractIfCan : (% , %) -> Union(%, "failed")

=====

**XFreeAlgebra examples**

=====

This category specifies operations for polynomials and formal series with non-commutative variables.

See Also:  
o )show XFreeAlgebra

---

**See:**

⇒ “XPolynomialsCat” (XPOLYC) [12](#) on page [1155](#)  
⇐ “RetractableTo” (RETRACT) [2](#) on page [102](#)  
⇐ “Ring” (RING) [9](#) on page [834](#)  
⇐ “XAlgebra” (XALG) [10](#) on page [1004](#)

**Exports:**

0	1	characteristic	coef	coerce
constant	constant?	hash	latex	lquo
map	mindeg	mindegTerm	mirror	monom
monomial?	one?	quasiRegular	quasiRegular?	recip
retract	retractIfCan	rquo	sample	sh
subtractIfCan	varList	zero?	???	???
?+?	?-?	-?	?=?	?^?
?^=?				

**Attributes Exported:**

- if Ring has noZeroDivisors then noZeroDivisors where **noZeroDivisors** is true if  $x*y \neq 0$  implies both x and y are non-zero.

- **commutative**("\*") is true if it has an operation " $*$ " :  $(D, D) \rightarrow D$  which is commutative.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation **recip** can only return "failed" if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .

These are directly exported but not implemented:

```

coef : (% , OrderedFreeMonoid v1) -> R
coef : (% , %) -> R
coerce : v1 -> %
constant : % -> R
constant? : % -> Boolean
lquo : (% , v1) -> %
lquo : (% , %) -> %
lquo : (% , OrderedFreeMonoid v1) -> %
map : ((R -> R) , %) -> %
mindeg : % -> OrderedFreeMonoid v1
mindegTerm : % -> Record(k: OrderedFreeMonoid v1, c: R)
mirror : % -> %
monom : (OrderedFreeMonoid v1, R) -> %
monomial? : % -> Boolean
quasiRegular : % -> %
quasiRegular? : % -> Boolean
rquo : (% , OrderedFreeMonoid v1) -> %
rquo : (% , %) -> %
rquo : (% , v1) -> %
sh : (% , NonNegativeInteger) -> % if R has COMRING
sh : (% , %) -> % if R has COMRING
varList : % -> List v1
?? : (v1, %) -> %
?? : (% , R) -> %

```

These exports come from (p834) Ring():

```

0 : () -> %
1 : () -> %
characteristic : () -> NonNegativeInteger
coerce : % -> OutputForm
coerce : Integer -> %
hash : % -> SingleInteger
latex : % -> String
one? : % -> Boolean
recip : % -> Union(% , "failed")
sample : () -> %
subtractIfCan : (% , %) -> Union(% , "failed")

```

```

zero? : % -> Boolean
?+? : (%,% ) -> %
?= ? : (%,% ) -> Boolean
?~=? : (%,% ) -> Boolean
?*? : (NonNegativeInteger,% ) -> %
?*? : (PositiveInteger,% ) -> %
?*? : (Integer,% ) -> %
?*? : (%,% ) -> %
?-? : (%,% ) -> %
-? : % -> %
?*** : (% ,PositiveInteger) -> %
?*** : (% ,NonNegativeInteger) -> %
?^? : (% ,NonNegativeInteger) -> %
?^? : (% ,PositiveInteger) -> %

```

These exports come from (p1004) XAlgebra(a:Ring):

```

coerce : R -> %
?*? : (R,% ) -> %

```

These exports come from (p102) RetractableTo(WORD)  
where WORD:OrderedFreeMonoid(OrderedSet))

```

coerce : OrderedFreeMonoid v1 -> %
retract : % -> OrderedFreeMonoid v1
retractIfCan : % -> Union(OrderedFreeMonoid v1,"failed")

```

Attributes Exported:

- `finiteAggregate` is true if it is an aggregate with a finite number of elements.

- if #2 has commutativeRing then commutative(“\*”) where **commutative**(“\*”) is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- if #2 has unitsKnown then unitsKnown where **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation **recip** can only return “failed” if its argument is not a unit.
- if #2 has Ring then rightUnitary where **leftUnitary** is true if  $1 * x = x$  for all x.
- if #2 has Ring then rightUnitary where **rightUnitary** is true if  $x * 1 = x$  for all x.
- **nil**

These are directly exported but not implemented:

```
directProduct : Vector R -> %
dot : (%,% ) -> R if R has RING
unitVector : PositiveInteger -> % if R has RING
?*? : (R,% ) -> % if R has MONOID
?*? : (% ,R) -> % if R has MONOID
```

These are implemented by this category:

```
characteristic : () -> NonNegativeInteger if R has RING
coerce : Integer -> %
  if and(has(R,RetractableTo Integer),
        has(R,SetCategory))
  or R has RING
differentiate : (% ,(R -> R)) -> % if R has RING
dimension : () -> CardinalNumber if R has FIELD
reducedSystem : Matrix % -> Matrix R if R has RING

=====
DivisionRing examples
=====

```

A division ring (sometimes called a skew field), i.e. a not necessarily commutative ring where all non-zero elements have multiplicative inverses.

See Also:  
o )show DivisionRing

---

See:

⇒ “Field” (FIELD) [16](#) on page [1283](#)  
⇐ “Algebra” (ALGEBRA) [11](#) on page [1009](#)  
⇐ “EntireRing” (ENTIRER) [10](#) on page [917](#)

**Exports:**

1	0	characteristic	coerce	hash
inv	latex	one?	recip	sample
subtractIfCan	zero?	?^?	?~=?	???
?*?	?+?	?-?	-?	?=?

**Attributes exported:**

- **noZeroDivisors** is true if  $x * y \neq 0$  implies both  $x$  and  $y$  are non-zero.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has `unitsKnown` means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .
- **nil**

These are directly exported but not implemented:

```
inv : % -> %
```

These are implemented by this category:

```
?^? : (%,Integer) -> %
?**? : (%,Integer) -> %
```

These exports come from (p917) `EntireRing()`:

```
0 : () -> %
1 : () -> %
characteristic : () -> NonNegativeInteger
coerce : Integer -> %
coerce : % -> OutputForm
hash : % -> SingleInteger
latex : % -> String
one? : % -> Boolean
recip : % -> Union(%, "failed")
sample : () -> %
subtractIfCan : (%,% ) -> Union(%, "failed")
zero? : % -> Boolean
?+? : (%,% ) -> %
?=? : (%,% ) -> Boolean
?~=? : (%,% ) -> Boolean
?*? : (%,% ) -> %
?*? : (Integer,% ) -> %
?*? : (PositiveInteger,% ) -> %
?*? : (NonNegativeInteger,% ) -> %
?-? : (%,% ) -> %
-? : % -> %
?^? : (% ,PositiveInteger) -> %
?^? : (% ,NonNegativeInteger) -> %
?***? : (% ,NonNegativeInteger) -> %
?***? : (% ,PositiveInteger) -> %
```

These exports come from (p1009) Algebra(Fraction(Integer)):

```
coerce : Fraction Integer -> %
???: (% , Fraction Integer) -> %
???: (Fraction Integer, %) -> %
```

— category DIVRING DivisionRing —

```
)abbrev category DIVRING DivisionRing
++ Description:
++ A division ring (sometimes called a skew field),

++   Lecture Notes Univ. Duesseldorf 1991
++ Description:
++ A FiniteRankNonAssociativeAlgebra is a non associative algebra over
++ a commutative ring R which is a free \spad{R}-module of finite rank.

FiniteRankNonAssociativeAlgebra(R:CommutativeRing):
  Category == NonAssociativeAlgebra R with

  someBasis : () -> Vector %
    ++ someBasis() returns some \spad{R}-module basis.

  rank : () -> PositiveInteger

```

```

++ rank() returns the rank of the algebra as \spad{R}-module.

conditionsForIdempotents: Vector % -> List Polynomial R
++ conditionsForIdempotents([v1,...,vn]) determines a complete list
++ of polynomial equations for the coefficients of idempotents
++ with respect to the \spad{R}-module basis \spad{v1},...,\spad{vn}.

structuralConstants: Vector % -> Vector Matrix R
++ structuralConstants([v1,v2,...,vm]) calculates the structural
++ constants \spad{[(gammaijk) for k in 1..m]} defined by
++ \spad{vi * vj = gammaij1 * v1 + ... + gammaijm * vm},
++ where \spad{[v1,...,vm]} is an \spad{R}-module basis
++ of a subalgebra.

leftRegularRepresentation: (% , Vector %) -> Matrix R
++ leftRegularRepresentation(a,[v1,...,vn]) returns the matrix of
++ the linear map defined by left multiplication by \spad{a}
++ with respect to the \spad{R}-module basis \spad{[v1,...,vn]}.

rightRegularRepresentation: (% , Vector %) -> Matrix R
++ rightRegularRepresentation(a,[v1,...,vn]) returns the matrix of
++ the linear map defined by right multiplication by \spad{a}
++ with respect to the \spad{R}-module basis \spad{[v1,...,vn]}.

leftTrace: % -> R
++ leftTrace(a) returns the trace of the left regular representation
++ of \spad{a}.

rightTrace: % -> R
++ rightTrace(a) returns the trace of the right regular representation
++ of \spad{a}.

leftNorm: % -> R
++ leftNorm(a) returns the determinant of the left regular
++ representation of \spad{a}.

rightNorm: % -> R
++ rightNorm(a) returns the determinant of the right regular
++ representation of \spad{a}.

coordinates: (% , Vector %) -> Vector R
++ coordinates(a,[v1,...,vn]) returns the coordinates of \spad{a}
++ with respect to the \spad{R}-module basis \spad{v1},...,\spad{vn}.

coordinates: (Vector % , Vector %) -> Matrix R
++ coordinates([a1,...,am],[v1,...,vn]) returns a matrix whose
++ i-th row is formed by the coordinates of \spad{ai}
++ with respect to the \spad{R}-module basis \spad{v1},...,\spad{vn}.

represents: (Vector R, Vector %) -> %

```

```

++ represents([a1,...,am],[v1,...,vm]) returns the linear
++ combination \spad{a1*vm + ... + an*vm}.

leftDiscriminant: Vector % -> R
++ leftDiscriminant([v1,...,vn]) returns the determinant of the
++ \spad{n}-by-\spad{n} matrix whose element at the \spad{i}-th row
++ and \spad{j}-th column is given by the left trace of the product
++ \spad{vi*vj}. Note that this is the same as
++ \spad{determinant(leftTraceMatrix([v1,...,vn]))}.

rightDiscriminant: Vector % -> R
++ rightDiscriminant([v1,...,vn]) returns the determinant of the
++ \spad{n}-by-\spad{n} matrix whose element at the \spad{i}-th row
++ and \spad{j}-th column is given by the right trace of the product
++ \spad{vi*vj}. Note that this is the same as
++ \spad{determinant(rightTraceMatrix([v1,...,vn]))}.

leftTraceMatrix: Vector % -> Matrix R
++ leftTraceMatrix([v1,...,vn]) is the \spad{n}-by-\spad{n} matrix
++ whose element at the \spad{i}-th row and \spad{j}-th column is given
++ by the left trace of the product \spad{vi*vj}.

rightTraceMatrix: Vector % -> Matrix R
++ rightTraceMatrix([v1,...,vn]) is the \spad{n}-by-\spad{n} matrix
++ whose element at the \spad{i}-th row and \spad{j}-th column is given
++ by the right trace of the product \spad{vi*vj}.

leftCharacteristicPolynomial: % -> SparseUnivariatePolynomial R
++ leftCharacteristicPolynomial(a) returns the characteristic
++ polynomial of the left regular representation of \spad{a}
++ with respect to any basis.

rightCharacteristicPolynomial: % -> SparseUnivariatePolynomial R
++ rightCharacteristicPolynomial(a) returns the characteristic
++ polynomial of the right regular representation of \spad{a}
++ with respect to any basis.

--we not necessarily have a unit
--if R has CharacteristicZero then CharacteristicZero
--if R has CharacteristicNonZero then CharacteristicNonZero

commutative?:()-> Boolean
++ commutative?() tests if multiplication in the algebra
++ is commutative.

antiCommutative?:()-> Boolean
++ antiCommutative?() tests if \spad{a*a = 0}
++ for all \spad{a} in the algebra.
++ Note that this implies \spad{a*b + b*a = 0} for all
++ \spad{a} and \spad{b}.

```

```

associative?:()-> Boolean
  ++ associative?() tests if multiplication in algebra
  ++ is associative.

antiAssociative?:()-> Boolean
  ++ antiAssociative?() tests if multiplication in algebra
  ++ is anti-associative, that is, \spad{(a*b)*c + a*(b*c) = 0}
  ++ for all \spad{a},b,c in the algebra.

leftAlternative?: ()-> Boolean
  ++ leftAlternative?() tests if \spad{2*associator(a,a,b) = 0}
  ++ for all \spad{a}, b in the algebra.
  ++ Note that we only can test this; in general we don't know
  ++ whether \spad{2*a=0} implies \spad{a=0}.

rightAlternative?: ()-> Boolean
  ++ rightAlternative?() tests if \spad{2*associator(a,b,b) = 0}
  ++ for all \spad{a}, b in the algebra.
  ++ Note that we only can test this; in general we don't know
  ++ whether \spad{2*a=0} implies \spad{a=0}.

flexible?: ()-> Boolean
  ++ flexible?() tests if \spad{2*associator(a,b,a) = 0}
  ++ for all \spad{a}, b in the algebra.
  ++ Note that we only can test this; in general we don't know
  ++ whether \spad{2*a=0} implies \spad{a=0}.

alternative?: ()-> Boolean
  ++ alternative?() tests if
  ++ \spad{2*associator(a,a,b) = 0 = 2*associator(a,b,b)}
  ++ for all \spad{a}, b in the algebra.
  ++ Note that we only can test this; in general we don't know
  ++ whether \spad{2*a=0} implies \spad{a=0}.

powerAssociative?:()-> Boolean
  ++ powerAssociative?() tests if all subalgebras
  ++ generated by a single element are associative.

jacobiIdentity?:() -> Boolean
  ++ jacobiIdentity?() tests if \spad{(a*b)*c + (b*c)*a + (c*a)*b = 0}
  ++ for all \spad{a},b,c in the algebra. For example, this holds
  ++ for crossed products of 3-dimensional vectors.

lieAdmissible?: () -> Boolean
  ++ lieAdmissible?() tests if the algebra defined by the commutators
  ++ is a Lie algebra, that is, satisfies the Jacobi identity.
  ++ The property of anticommutativity follows from definition.

jordanAdmissible?: () -> Boolean

```

```

++ jordanAdmissible?() tests if 2 is invertible in the
++ coefficient domain and the multiplication defined by
++ \spad{(1/2)(a*b+b*a)} determines a
++ Jordan algebra, that is, satisfies the Jordan identity.
++ The property of \spadatt{commutative("*")}
++ follows from by definition.

noncommutativeJordanAlgebra?: () -> Boolean
++ noncommutativeJordanAlgebra?() tests if the algebra
++ is flexible and Jordan admissible.

jordanAlgebra?:() -> Boolean
++ jordanAlgebra?() tests if the algebra is commutative,
++ characteristic is not 2, and \spad{(a*b)*a**2 - a*(b*a**2) = 0}
++ for all \spad{a},b,c in the algebra (Jordan identity).
++ Example:
++ for every associative algebra \spad{(A,+,@)} we can construct a
++ Jordan algebra \spad{(A,+,*)}, where \spad{a*b := (a@b+b@a)/2}.

lieAlgebra?:() -> Boolean
++ lieAlgebra?() tests if the algebra is anticommutative
++ and \spad{(a*b)*c + (b*c)*a + (c*a)*b = 0}
++ for all \spad{a},b,c in the algebra (Jacobi identity).
++ Example:
++ for every associative algebra \spad{(A,+,@)} we can construct a
++ Lie algebra \spad{(A,+,*)}, where \spad{a*b := a@b-b@a}.

if R has IntegralDomain then

-- we not necessarily have a unit, hence we don't inherit
-- the next 3 functions anc hence copy them from MonadWithUnit:

recip: % -> Union(%, "failed")
++ recip(a) returns an element, which is both a left and a right
++ inverse of \spad{a},
++ or \spad{"failed"} if there is no unit element, if such an
++ element doesn't exist or cannot be determined (see unitsKnown).

leftRecip: % -> Union(%, "failed")
++ leftRecip(a) returns an element, which is a left inverse of
++ \spad{a}, or \spad{"failed"} if there is no unit element, if such
++ an element doesn't exist or cannot be determined (see unitsKnown).

rightRecip: % -> Union(%, "failed")
++ rightRecip(a) returns an element, which is a right inverse of
++ \spad{a},
++ or \spad{"failed"} if there is no unit element, if such an
++ element doesn't exist or cannot be determined (see unitsKnown).

associatorDependence:() -> List Vector R

```

```

++ associatorDependence() looks for the associator identities, that
++ is, finds a basis of the solutions of the linear combinations of the
++ six permutations of \spad{associator(a,b,c)} which yield 0,
++ for all \spad{a},b,c in the algebra.
++ The order of the permutations is \spad{123 231 312 132 321 213}.

leftMinimalPolynomial : % -> SparseUnivariatePolynomial R
++ leftMinimalPolynomial(a) returns the polynomial determined by the
++ smallest non-trivial linear combination of left powers of
++ \spad{a}. Note that the polynomial never has a constant term as in
++ general the algebra has no unit.

rightMinimalPolynomial : % -> SparseUnivariatePolynomial R
++ rightMinimalPolynomial(a) returns the polynomial determined by the
++ smallest non-trivial linear
++ combination of right powers of \spad{a}.
++ Note that the polynomial never has a constant term as in general
++ the algebra has no unit.

leftUnits() -> Union(Record(particular: %, basis: List %), "failed")
++ leftUnits() returns the affine space of all left units of the
++ algebra, or \spad{"failed"} if there is none.

rightUnits() -> Union(Record(particular: %, basis: List %), "failed")
++ rightUnits() returns the affine space of all right units of the
++ algebra, or \spad{"failed"} if there is none.

leftUnit() -> Union(%, "failed")
++ leftUnit() returns a left unit of the algebra
++ (not necessarily unique), or \spad{"failed"} if there is none.

rightUnit() -> Union(%, "failed")
++ rightUnit() returns a right unit of the algebra
++ (not necessarily unique), or \spad{"failed"} if there is none.

unit() -> Union(%, "failed")
++ unit() returns a unit of the algebra (necessarily unique),
++ or \spad{"failed"} if there is none.

-- we not necessarily have a unit, hence we can't say anything
-- about characteristic
-- if R has CharacteristicZero then CharacteristicZero
-- if R has CharacteristicNonZero then CharacteristicNonZero

unitsKnown
++ unitsKnown means that \spadfun{recip} truly yields reciprocal
++ or \spad{"failed"} if not a unit,
++ similarly for \spadfun{leftRecip} and
++ \spadfun{rightRecip}. The reason is that we use left, respectively
++ right, minimal polynomials to decide this question.

=====
FreeLieAlgebra examples
=====
```

The category of free Lie algebras. It is used by domains of non-commutative algebra such as LiePolynomial and XPBWPolynomial.

See Also:

o )show FreeLieAlgebra

See:

⇐ “LieAlgebra” (LIECAT) 11 on page 1028

**Exports:**

0	coef	coerce	construct	degree
eval	hash	latex	LiePoly	lquo
mirror	rquo	sample	subtractIfCan	trunc
varList	zero?	?~=?	?*?	?/?
?+?	?-?	-?	?=?	

**Attributes Exported:**

- **NullSquare** means that  $[x, x] = 0$  holds. See LieAlgebra.
- **JacobiIdentity** means that  $[x, [y, z]] + [y, [z, x]] + [z, [x, y]] = 0$  holds. See LieAlgebra.
- **leftUnitary** is true if  $1 * x = x$  for all x.
- **rightUnitary** is true if  $x * 1 = x$  for all x.

These are directly exported but not implemented:

```
coef : (XRecursivePolynomial(VarSet,R),%) -> R
coerce : VarSet -> %
coerce : % -> XRecursivePolynomial(VarSet,R)
coerce : % -> XDistributedPolynomial(VarSet,R)
degree : % -> NonNegativeInteger
eval : (%,List VarSet,List %) -> %
eval : (% ,VarSet,%) -> %
LiePoly : LyndonWord VarSet -> %
lquo : (XRecursivePolynomial(VarSet,R),%) -> XRecursivePolynomial(VarSet,R)
mirror : % -> %
rquo : (XRecursivePolynomial(VarSet,R),%) -> XRecursivePolynomial(VarSet,R)
trunc : (% ,NonNegativeInteger) -> %
varList : % -> List VarSet
```

These exports come from (p1028) LieAlgebra(CommutativeRing):

```

0 : () -> %
coerce : % -> OutputForm
construct : (%,% ) -> %
hash : % -> SingleInteger
latex : % -> String
sample : () -> %
subtractIfCan : (%,% ) -> Union(%, "failed")
zero? : % -> Boolean
?/? : (% , R) -> % if R has FIELD
?~=? : (% , % ) -> Boolean
?*? : (NonNegativeInteger , % ) -> %
?*? : (% , R) -> %
?*? : (R , % ) -> %
?*? : (Integer , % ) -> %
?*? : (PositiveInteger , % ) -> %
?+? : (% , % ) -> %
?-? : (% , % ) -> %
-? : % -> %
?=? : (% , % ) -> Boolean

```

++ Author: Michel Petitot (petitot@lifl.fr)
++ Date Created: 91
++ Date Last Updated: 7 Juillet 92
++ Fix History: compilation v 2.1 le 13 dec 98
++ Description:
++ The category of free Lie algebras.
++ It is used by domains of non-commutative algebra:
++ \spadtype{LiePolynomial} and
++ \spadtype{XPBWPolynomial}.

FreeLieAlgebra(VarSet:OrderedSet, R:CommutativeRing) :Category == _
CatDef where
  XRPOLY ==> XRecursivePolynomial(VarSet,R)
  XDPOLY ==> XDistributedPolynomial(VarSet,R)
  RN      ==> Fraction Integer
  LWORD   ==> LyndonWord(VarSet)

CatDef == Join(LieAlgebra(R)) with
  coef      : (XRPOLY , $) -> R
  ++ \axiom{coef(x,y)} returns the scalar product of \axiom{x} by
  ++ \axiom{y}, the set of words being regarded as an orthogonal basis.
  coerce    : VarSet -> $
  ++ \axiom{coerce(x)} returns \axiom{x} as a Lie polynomial.
  coerce    : $ -> XDPOLY

```

```

++ \axiom{coerce(x)} returns \axiom{x} as distributed polynomial.
coerce      : $ -> XRPOLY
++ \axiom{coerce(x)} returns \axiom{x} as a recursive polynomial.
degree      : $ -> NonNegativeInteger
++ \axiom{degree(x)} returns the greatest length of a word in the
++ support of \axiom{x}.
--if R has Module(RN) then
-- Hausdorff : ($,$,PositiveInteger) -> $
lquo        : (XRPOLY , $) -> XRPOLY
++ \axiom{lquo(x,y)} returns the left simplification of \axiom{x}
++ by \axiom{y}.
rquo        : (XRPOLY , $) -> XRPOLY
++ \axiom{rquo(x,y)} returns the right simplification of \axiom{x}
++ by \axiom{y}.
LiePoly     : LWORD -> $
++ \axiom{LiePoly(l)} returns the bracketed form of \axiom{l} as
++ a Lie polynomial.
mirror      : $ -> $
++ \axiom{mirror(x)} returns \axiom{Sum(r_i mirror(w_i))}
++ if \axiom{x} is \axiom{Sum(r_i w_i)}.
trunc       : ($, NonNegativeInteger) -> $
++ \axiom{trunc(p,n)} returns the polynomial \axiom{p}
++ truncated at order \axiom{n}.
varList     : $ -> List VarSet
++ \axiom{varList(x)} returns the list of distinct entries
++ of \axiom{x}.
eval        : ($, VarSet, $) -> $
++ \axiom{eval(p, x, v)} replaces \axiom{x} by \axiom{v}
++ in \axiom{p}.
eval        : ($, List VarSet, List $) -> $
++ \axiom{eval(p, [x1,...,xn], [v1,...,vn])} replaces \axiom{xi}
++ by \axiom{vi} in \axiom{p}.

=====
IntegralDomain examples
=====

```

The category of commutative integral domains, i.e. commutative rings with no zero divisors. That means that we can show that if  $ab = 0$  then either  $a$  or  $b$  must be 0.

This does not have to be true. For instance, real 2x2 matrices have zero divisors since

$$\begin{array}{cccccc}
 A & x & B & = & 0 & \text{but neither } A \text{ nor } B \text{ is } 0: \\
 +- & +- & +- & +- & +- & +- \\
 | 0 & 1 & | & | 0 & 2 & | = | 0 & 0 & | \\
 | 0 & 0 & | & | 0 & 0 & | & | 0 & 0 & | \\
 +- & +- & +- & +- & +- & +-
 \end{array}$$

Conditional attributes:

```

canonicalUnitNormal - the canonical field is the same for all associates
canonicalsClosed    - the product of two canonicals is itself canonical

```

```

Ring -> CommutativeRing -> IntegralDomain

```

- 1) (associative addition)  $a + (b + c) = (a + b) + c$
- 2) (commutative addition)  $a + b = b + a$
- 3) (associative multiplication)  $a(bc) = (ab)c$
- 4) (distributive multiplication)  $a(b + c) = ab + ac$ ;  $(b + c)a = ba + ca$
- 5) (equation solution)  $a + x = b$  has a solution in  $R$

Exports:

0	1	associates?	characteristic	coerce
exquo	hash	latex	one?	recip
sample	subtractIfCan	unit?	unitCanonical	unitNormal
zero?	?~=?	?*?	?**?	?^?
?+?	?-?	-?	?=?	

Attributes exported:

- **noZeroDivisors** is true if  $x * y \neq 0$  implies both  $x$  and  $y$  are non-zero.
- **commutative(“\*”)** is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation **recip** can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .

Attributes Used:

- **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is `associates?(a,b)` returns true if and only if `unitCanonical(a) = unitCanonical(b)`.

These are directly exported but not implemented:

```
exquo : (%,%) -> Union(%, "failed")
```

These are implemented by this category:

```
associates? : (%,%) -> Boolean
unit? : % -> Boolean
unitCanonical : % -> %
unitNormal : % -> Record(unit: %, canonical: %, associate: %)
```

These exports come from (p906) `CommutativeRing()`:

```
0 : () -> %
1 : () -> %
characteristic : () -> NonNegativeInteger
coerce : Integer -> %
coerce : % -> OutputForm
hash : % -> SingleInteger
latex : % -> String
one? : % -> Boolean
recip : % -> Union(%, "failed")
sample : () -> %
subtractIfCan : (%,%) -> Union(%, "failed")
zero? : % -> Boolean
?+? : (%,%) -> %
?=? : (%,%) -> Boolean
?~=? : (%,%) -> Boolean
?*? : (%,%) -> %
?*? : (Integer,%) -> %
?*? : (NonNegativeInteger,%) -> %
?*? : (PositiveInteger,%) -> %
?-? : (%,%) -> %
-? : % -> %
?^? : (%, NonNegativeInteger) -> %
?^? : (%, PositiveInteger) -> %
?***? : (%, NonNegativeInteger) -> %
?***? : (%, PositiveInteger) -> %
```

TPDHERE: Should we construct this coercion?

These exports come from (p1009) `Algebra(a: IntegralDomain)`:

```
coerce : % -> %
```

```

=====
MonogenicLinearOperator examples
=====

```

This is the category of linear operator rings with one generator.  
The generator is not named by the category but can always be  
constructed as monomial(1,1).

For convenience, call the generator G.  
Then each value is equal to  
 $\text{sum}(a(i)*G^{**i}, i = 0..n)$   
for some unique n and a(i) in R.

Note that multiplication is not necessarily commutative.  
 In fact, if  $a$  is in  $R$ , it is quite normal to have  $a \cdot G \neq G \cdot a$ .

**Exports:**

0	1	abs	characteristic	charthRoot
coerce	conjugate	convert	eval	hash
imagE	imagI	imagJ	imagK	imagi
imagj	imagk	index	inv	latex
lookup	map	max	min	norm
octon	one?	random	rational	rational?
rationalIfCan	real	recip	retract	retractIfCan
sample	size	subtractIfCan	zero?	?*?
?**?	?+?	?-?	-?	?=?
?^?	?^=?	?<?	?<=?	?>?
?>=?	?.??			

### Attributes Exported:

- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all x.
- **rightUnitary** is true if  $x * 1 = x$  for all x.

These are directly exported but not implemented:

```

imagi : % -> R
imagj : % -> R
imagk : % -> R
imagE : % -> R
imagI : % -> R
imagJ : % -> R
imagK : % -> R
octon : (R,R,R,R,R,R,R,R) -> %
real : % -> R

```

These are implemented by this category:

```

abs : % -> R if R has RNS
characteristic : () -> NonNegativeInteger
coerce : R -> %
coerce : Integer -> %
coerce : % -> OutputForm
conjugate : % -> %
convert : % -> InputForm if R has KONVERT INFORM
inv : % -> % if R has FIELD
map : ((R -> R),%) -> %
norm : % -> R
rational : % -> Fraction Integer if R has INS
rational? : % -> Boolean if R has INS
rationalIfCan : % -> Union(Fraction Integer,"failed") if R has INS
retract : % -> R

```

```

retractIfCan : % -> Union(R,"failed")
zero? : % -> Boolean
?<? : (%,% ) -> Boolean if R has ORDSET
?=? : (%,% ) -> Boolean
?+? : (%,% ) -> %
-? : % -> %
?*? : (R,% ) -> %
?*? : (Integer,% ) -> %

```

These exports come from (p1009) Algebra(R:CommutativeRing):

```

0 : () -> %
1 : () -> %
hash : % -> SingleInteger
latex : % -> String
one? : % -> Boolean
recip : % -> Union(%,"failed")

++ Author: R. Wisbauer, J. Grabmeier
++ Date Created: 05 September 1990
++ Date Last Updated: 19 September 1990
++ References: e.g. I.L. Kantor, A.S. Solodovnikov:
++ Hypercomplex Numbers, Springer Verlag Heidelberg, 1989,
++ ISBN 0-387-96980-2
++ Description:
++ OctonionCategory gives the categorial frame for the
++ octonions, and eight-dimensional non-associative algebra,
++ doubling the the quaternions in the same way as doubling
++ the Complex numbers to get the quaternions.

OctonionCategory(R: CommutativeRing): Category ==
-- we are cheating a little bit, algebras in \Language{}
-- are mainly considered to be associative, but that's not
-- an attribute and we can't guarantee that there is no piece
-- of code which implicitly
-- uses this. In a later version we shall properly combine
-- all this code in the context of general, non-associative
-- algebras, which are meanwhile implemented in \Language{}
Join(Algebra R, FullyRetractableTo R, FullyEvalableOver R) with
conjugate: % -> %
++ conjugate(o) negates the imaginary parts i,j,k,E,I,J,K of octonian o.
real: % -> R
++ real(o) extracts real part of octonion o.
imagi: % -> R
++ imagi(o) extracts the i part of octonion o.
imagj: % -> R

```

```

    ++ imagj(o) extracts the j part of octonion o.
imagk: % -> R
    ++ imagk(o) extracts the k part of octonion o.
imagE: % -> R
    ++ imagE(o) extracts the imaginary E part of octonion o.
imagI: % -> R
    ++ imagI(o) extracts the imaginary I part of octonion o.
imagJ: % -> R
    ++ imagJ(o) extracts the imaginary J part of octonion o.
imagK: % -> R
    ++ imagK(o) extracts the imaginary K part of octonion o.
norm: % -> R
    ++ norm(o) returns the norm of an octonion, equal to
    ++ the sum of the squares
    ++ of its coefficients.
octon: (R,R,R,R,R,R,R,R) -> %
    ++ octon(re,ri,rj,rk,rE,rI,rJ,rK) constructs an octonion
    ++ from scalars.
if R has Finite then Finite
if R has OrderedSet then OrderedSet
if R has ConvertibleTo InputForm then ConvertibleTo InputForm
if R has CharacteristicZero then CharacteristicZero
if R has CharacteristicNonZero then CharacteristicNonZero
if R has RealNumberSystem then
abs: % -> R
    ++ abs(o) computes the absolute value of an octonion, equal to
    ++ the square root of the \spadfunFrom{norm}{Octonion}.
if R has IntegerNumberSystem then
rational? : % -> Boolean
    ++ rational?(o) tests if o is rational, i.e. that all seven
    ++ imaginary parts are 0.
rational : % -> Fraction Integer
    ++ rational(o) returns the real part if all seven
    ++ imaginary parts are 0.
    ++ Error: if o is not rational.
rationalIfCan: % -> Union(Fraction Integer, "failed")
    ++ rationalIfCan(o) returns the real part if
    ++ all seven imaginary parts are 0, and "failed" otherwise.
if R has Field then
inv : % -> %
    ++ inv(o) returns the inverse of o if it exists.

**Attributes Exported:**

- if #1 has EntireRing then noZeroDivisors where **noZeroDivisors** is true if  $x * y \neq 0$  implies both x and y are non-zero.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation **recip** can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all x.
- **rightUnitary** is true if  $x * 1 = x$  for all x.

These are directly exported but not implemented:

```

imagI : % -> R
imagJ : % -> R
imagK : % -> R
quatern : (R,R,R,R) -> %
real : % -> R

```

These are implemented by this category:

```

abs : % -> R if R has RNS
characteristic : () -> NonNegativeInteger
coerce : R -> %
coerce : Integer -> %
coerce : % -> OutputForm
conjugate : % -> %
convert : % -> InputForm if R has KONVERT INFORM
differentiate : (%,(R -> R)) -> %
inv : % -> % if R has FIELD
map : ((R -> R),%) -> %
norm : % -> R
one? : % -> Boolean
rational : % -> Fraction Integer if R has INS
rational? : % -> Boolean if R has INS
rationalIfCan : % -> Union(Fraction Integer,"failed") if R has INS
retract : % -> R
retractIfCan : % -> Union(R,"failed")

```

These exports come from (p897) CharacteristicNonZero():

```
charthRoot : % -> Union(%, "failed") if R has CHARNZ
```

— category QUATCAT QuaternionCategory —

```
)abbrev category QUATCAT QuaternionCategory
++ Author: Robert S. Sutor
++ Date Created: 23 May 1990
++ Change History: 10 September 1990
++ Description:
++ \spadtype{QuaternionCategory} describes the category of quaternions
++ and implements functions that are not representation specific.

QuaternionCategory(R: CommutativeRing): Category ==
  Join(Algebra R, FullyRetractableTo R, DifferentialExtension R,
    FullyEvaluableOver R, FullyLinearlyExplicitRingOver R) with

  conjugate: $ -> $
    ++ conjugate(q) negates the imaginary parts of quaternion \spad{q}.
  imagI: $ -> R
    ++ imagI(q) extracts the imaginary i part of quaternion \spad{q}.
  imagJ: $ -> R
    ++ imagJ(q) extracts the imaginary j part of quaternion \spad{q}.
  imagK: $ -> R
    ++ imagK(q) extracts the imaginary k part of quaternion \spad{q}.
  norm: $ -> R
    ++ norm(q) computes the norm of \spad{q} (the sum of the
    ++ squares of the components).
  quatern: (R,R,R,R) -> $
    ++ quatern(r,i,j,k) constructs a quaternion from scalars.
  real: $ -> R
    ++ real(q) extracts the real part of quaternion \spad{q}.

  if R has EntireRing then EntireRing
  if R has OrderedSet then OrderedSet
  if R has Field then DivisionRing
  if R has ConvertibleTo InputForm then ConvertibleTo InputForm
  if R has CharacteristicZero then CharacteristicZero
  if R has CharacteristicNonZero then CharacteristicNonZero
  if R has RealNumberSystem then
```

```

abs      : $ -> R
++ abs(q) computes the absolute value of quaternion \spad{q}
++ (sqrt of norm).
if R has IntegerNumberSystem then
rational? : $ -> Boolean
++ rational?(q) returns {\it true} if all the imaginary
++ parts of \spad{q} are zero and the real part can be
++ converted into a rational number, and {\it false}
++ otherwise.
rational  : $ -> Fraction Integer
++ rational(q) tries to convert \spad{q} into a
++ rational number. Error: if this is not
++ possible. If \spad{rational?(q)} is true, the
++ conversion will be done and the rational number returned.
rationalIfCan: $ -> Union(Fraction Integer, "failed")
++ rationalIfCan(q) returns \spad{q} as a rational number,
++ or "failed" if this is not possible.
++ Note that if \spad{rational?(q)} is true, the conversion
++ can be done and the rational number will be returned.

## SquareMatrixCategory (SMATCAT)

We define three categories for matrices

- MatrixCategory is the category of all matrices
- RectangularMatrixCategory is the category of all matrices of a given dimension
- SquareMatrixCategory inherits from RectangularMatrixCategory

The SquareMatrix domain is for square matrices of fixed dimension.

**Attributes Exported:**

- **finiteAggregate** is true if it is an aggregate with a finite number of elements.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has `unitsKnown` means that the operation `recip` can only return “failed” if its argument is not a unit.
- **nil**

TPDHERE: How did MATCAT get in the type tower?

```
determinant : % -> R if R has commutative *
inverse : % -> Union(,"failed") if R has FIELD
```

These are directly exported but not implemented:

```
diagonalMatrix : List R -> %
minordet : % -> R if R has commutative *
scalarMatrix : R -> %
?*? : (Row,% ) -> Row
?*? : (% ,Col) -> Col
```

These are implemented by this category:

```

coerce : R -> %

=====

XPolynomialsCat examples

=====

The Category of polynomial rings with non-commutative variables.  
The coefficient ring may be non-commutative too.  
However coefficients commute with variables.

See Also:

o )show XPolynomialsCat

---

**See:**

⇐ “XFreeAlgebra” (XFALG) [11](#) on page [1052](#)

**Exports:**

0	1	characteristic	coef	coerce
constant	constant?	degree	hash	latex
lquo	map	maxdeg	mindeg	mindegTerm
mirror	monom	monomial?	one?	quasiRegular
quasiRegular?	recip	retract	retractIfCan	rquo
sample	sh	subtractIfCan	trunc	varList
zero?	?*?	?**?	?+?	?-?
-?	?=?	?^?	?~=?	

**Attributes Exported:**

- if Ring has `noZeroDivisors` then `noZeroDivisors` where **noZeroDivisors** is true if  $x*y \neq 0$  implies both  $x$  and  $y$  are non-zero.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has `unitsKnown` means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .

These are directly exported but not implemented:

```
degree : % -> NonNegativeInteger
maxdeg : % -> OrderedFreeMonoid v1
trunc : (% , NonNegativeInteger) -> %
```

These exports come from (p[123](#)) `Aggregate()`:

=====
AbelianMonoidRing examples
=====

```

Abelian monoid ring elements (not necessarily of finite support) of this ring are of the form formal SUM ( $r_i * e_i$ ) where the  $r_i$  are coefficients and the  $e_i$ , elements of the ordered abelian monoid, are thought of as exponents or monomials. The monomials commute with each other, and with the coefficients (which themselves may or may not be commutative).

See `FiniteAbelianMonoidRing` for the case of finite support a useful common model for polynomials and power series. Conceptually at least, only the non-zero terms are ever operated on.

See Also:

o `show AbelianMonoidRing`

---

**See:**

⇒ “`FiniteAbelianMonoidRing`” (FAMR) [14](#) on page [1203](#)

⇒ “`PowerSeriesCategory`” (PSCAT) [14](#) on page [1220](#)

⇐ “`BiModule`” (BMODULE) [9](#) on page [790](#)

⇐ “`Ring`” (RING) [9](#) on page [834](#)

**Exports:**

0	1	associates?	characteristic
<code>charthRoot</code>	coefficient	coerce	degree
<code>exquo</code>	hash	latex	leadingCoefficient
<code>leadingMonomial</code>	map	monomial	monomial?
<code>one?</code>	recip	reductum	sample
<code>subtractIfCan</code>	unit?	unitCanonical	unitNormal
<code>zero?</code>	?*?	?**?	?+?
?-?	-?	?=?	?^?
?^=?	?/?		

**Attributes exported:**

- if \$ has `CommutativeRing` then `commutative(“*”)`  where **`commutative(“*”)`  is true if it has an operation “`*`” :  $(D, D) \rightarrow D$  which is commutative.**
- if \$ has `IntegralDomain` then `noZeroDivisors` where **`noZeroDivisors` is true if  $x*y \neq 0$  implies both x and y are non-zero.**
- **`unitsKnown`** is true if a monoid (a multiplicative semigroup with a 1) has `unitsKnown` means that the operation `recip` can only return “failed” if its argument is not a unit.
- **`leftUnitary`** is true if  $1 * x = x$  for all x.
- **`rightUnitary`** is true if  $x * 1 = x$  for all x.

These are directly exported but not implemented:

```
coefficient : (% , E) -> R
degree : % -> E
leadingCoefficient : % -> R
leadingMonomial : % -> %
monomial : (R, E) -> %
reductum : % -> %
?/? : (% , R) -> % if R has FIELD
```

These are implemented by this category:

```
map : ((R -> R), %) -> %
monomial? : % -> Boolean
?/? : (Fraction Integer, %) -> % if R has ALGEBRA FRAC INT
```

These exports come from (p834) Ring():

=====
FortranMachineTypeCategory examples
=====

```

A category of domains which model machine arithmetic used by machines in the AXIOM-NAG link.

See Also:

o )show FortranMachineTypeCategory

See:

⇐ “IntegralDomain” (INTDOM) 12 on page 1107

⇐ “OrderedSet” (ORDSET) 4 on page 278

⇐ “RetractableTo” (RETRACT) 2 on page 102

**Exports:**

0	1	associates?	characteristic	coerce
exquo	hash	latex	max	min
one?	recip	retract	retractIfCan	sample
subtractIfCan	unit?	unitCanonical	unitNormal	zero?
?~=?	?^?	?*?	?**?	?+?
?-?	?-?	?<?	?<=?	?=?
?>?	?>=?			

**Attributes Exported:**

- **noZeroDivisors** is true if  $x * y \neq 0$  implies both x and y are non-zero.
- **commutative(“\*”)** is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation **recip** can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all x.
- **rightUnitary** is true if  $x * 1 = x$  for all x.

These exports come from (p1107) IntegralDomain():

```
0 : () -> %
1 : () -> %
associates? : (%,% ) -> Boolean
characteristic : () -> NonNegativeInteger
coerce : Integer -> %
coerce : % -> OutputForm
coerce : % -> %
exquo : (%,% ) -> Union(%, "failed")
hash : % -> SingleInteger
```

```

latex : % -> String

— category FRNAALG FramedNonAssociativeAlgebra —

```

)abbrev category FRNAALG FramedNonAssociativeAlgebra
++ Author: J. Grabmeier, R. Wisbauer
++ Date Created: 01 March 1991
++ Date Last Updated: 11 June 1991
++ Reference:
++ R.D. Schafer: An Introduction to Nonassociative Algebras
++ Academic Press, New York, 1966
++ Description:
++ FramedNonAssociativeAlgebra(R) is a
++ \spadtype{FiniteRankNonAssociativeAlgebra} (i.e. a non associative
++ algebra over R which is a free \spad{R}-module of finite rank)
++ over a commutative ring R together with a fixed \spad{R}-module basis.

FramedNonAssociativeAlgebra(R:CommutativeRing):
  Category == FiniteRankNonAssociativeAlgebra(R) with
  basis: () -> Vector %
  ++ basis() returns the fixed \spad{R}-module basis.
  coordinates: % -> Vector R
  ++ coordinates(a) returns the coordinates of \spad{a}
  ++ with respect to the
  ++ fixed \spad{R}-module basis.
  coordinates: Vector % -> Matrix R
  ++ coordinates([a1,...,am]) returns a matrix whose i-th row
  ++ is formed by the coordinates of \spad{ai} with respect to the

```

```

++ fixed \spad{R}-module basis.
elt : (%,Integer) -> R
++ elt(a,i) returns the i-th coefficient of \spad{a} with respect
++ to the fixed \spad{R}-module basis.
structuralConstants:() -> Vector Matrix R
++ structuralConstants() calculates the structural constants
++ \spad{[(gamma_ijk) for k in 1..rank()]}, defined by
++ \spad{v_i * v_j = gamma_{ij1} * v_1 + ... + gamma_{ijn} * v_n},
++ where \spad{v_1}, ..., \spad{v_n} is the fixed \spad{R}-module basis.
conditionsForIdempotents: () -> List Polynomial R
++ conditionsForIdempotents() determines a complete list
++ of polynomial equations for the coefficients of idempotents
++ with respect to the fixed \spad{R}-module basis.
represents: Vector R -> %
++ represents([a_1, ..., a_n]) returns \spad{a_1*v_1 + ... + a_n*v_n},
++ where \spad{v_1}, ..., \spad{v_n} are the elements of the
++ fixed \spad{R}-module basis.
convert: % -> Vector R
++ convert(a) returns the coordinates of \spad{a} with respect to the
++ fixed \spad{R}-module basis.
convert: Vector R -> %
++ convert([a_1, ..., a_n]) returns \spad{a_1*v_1 + ... + a_n*v_n},
++ where \spad{v_1}, ..., \spad{v_n} are the elements of the
++ fixed \spad{R}-module basis.
leftDiscriminant : () -> R
++ leftDiscriminant() returns the
++ determinant of the \spad{n}-by-\spad{n}
++ matrix whose element at the \spad{i}-th row and \spad{j}-th column
++ is given by the left trace of the product \spad{v_i*v_j}, where
++ \spad{v_1}, ..., \spad{v_n} are the
++ elements of the fixed \spad{R}-module basis.
++ Note that the same as \spad{determinant(leftTraceMatrix())}.
rightDiscriminant : () -> R
++ rightDiscriminant() returns the determinant of the
++ \spad{n}-by-\spad{n} matrix whose element at the \spad{i}-th row
++ and \spad{j}-th column is
++ given by the right trace of the product \spad{v_i*v_j}, where
++ \spad{v_1}, ..., \spad{v_n} are the elements of
++ the fixed \spad{R}-module basis.
++ Note that the same as \spad{determinant(rightTraceMatrix())}.
leftTraceMatrix : () -> Matrix R
++ leftTraceMatrix() is the \spad{n}-by-\spad{n}
++ matrix whose element at the \spad{i}-th row and \spad{j}-th column
++ is given by left trace of the product \spad{v_i*v_j},
++ where \spad{v_1}, ..., \spad{v_n} are the
++ elements of the fixed \spad{R}-module basis.
rightTraceMatrix : () -> Matrix R
++ rightTraceMatrix() is the \spad{n}-by-\spad{n}
++ matrix whose element at the \spad{i}-th row and \spad{j}-th column
++ is given by the right trace of the product \spad{v_i*v_j}, where

```

```

++ \spad{v1},...,\spad{vn} are the elements
++ of the fixed \spad{R}-module basis.
leftRegularRepresentation : % -> Matrix R
++ leftRegularRepresentation(a) returns the matrix of the linear
++ map defined by left multiplication by \spad{a} with respect
++ to the fixed \spad{R}-module basis.
rightRegularRepresentation : % -> Matrix R
++ rightRegularRepresentation(a) returns the matrix of the linear
++ map defined by right multiplication by \spad{a} with respect
++ to the fixed \spad{R}-module basis.
if R has Field then
leftRankPolynomial : () -> SparseUnivariatePolynomial Polynomial R
++ leftRankPolynomial() calculates the left minimal polynomial
++ of the generic element in the algebra,
++ defined by the same structural
++ constants over the polynomial ring in symbolic coefficients with
++ respect to the fixed basis.
rightRankPolynomial : () -> SparseUnivariatePolynomial Polynomial R
++ rightRankPolynomial() calculates the right minimal polynomial
++ of the generic element in the algebra,
++ defined by the same structural
++ constants over the polynomial ring in symbolic coefficients with
++ respect to the fixed basis.
apply: (Matrix R, %) -> %
++ apply(m,a) defines a left operation of n by n matrices
++ where n is the rank of the algebra in terms of matrix-vector
++ multiplication, this is a substitute for a left module structure.
++ Error: if shape of matrix doesn't fit.

Exports:

0	1	associates?	characteristic	coerce
exquo	gcd	gcdPolynomial	hash	latex
lcm	one?	recip	sample	subtractIfCan
unit?	unitCanonical	unitNormal	zero?	?*?
?**?	?+?	?-?	-?	?=?
?^?	?~=?			

Attributes exported:

- **noZeroDivisors** is true if  $x * y \neq 0$  implies both x and y are non-zero.
- **commutative**(“\*\*”) is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation **recip** can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all x.
- **rightUnitary** is true if  $x * 1 = x$  for all x.

These are directly exported but not implemented:

gcd : (%,% ) -> %

These are implemented by this category:

```

gcd : List % -> %
gcdPolynomial : (SparseUnivariatePolynomial %,
                 SparseUnivariatePolynomial %) ->
                 SparseUnivariatePolynomial %
lcm : (%,% ) -> %
lcm : List % -> %

```

These exports come from (p1107) IntegralDomain():

```

 ⇐ “TranscendentalFunctionCategory” (TRANFUN) [3](#) on page [174](#)

**Exports:**

0	1	acos	acosh	acot
acoth	acsc	acsch	asec	asech
asin	asinh	associates?	atan	atanh
characteristic	coerce	contains?	cos	cosh
cot	coth	csc	csch	exp
exquo	gcd	gcdPolynomial	hash	inf
interval	latex	lcm	log	max
min	negative?	nthRoot	one?	pi
positive?	qinterval	recip	retract	retractIfCan
sample	sec	sech	sin	sinh
sqrt	subtractIfCan	sup	tan	tanh
unit?	unitCanonical	unitNormal	width	zero?
?*?	?**?	?+?	?-?	-?
?<?	?<=?	?=?	?>?	?>=?
?^?	?~=?			

**Attributes Exported:**

- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all x.
- **rightUnitary** is true if  $x * 1 = x$  for all x.
- **commutative(“\*\*”)** is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- **noZeroDivisors** is true if  $x * y \neq 0$  implies both x and y are non-zero.
- **approximate** means “is an approximation to the real numbers”.

TPDHERE: Note that the signature `coerce : Integer -> %` shows up twice.

These are directly exported but not implemented:

```
contains? : (% , R) -> Boolean
inf : % -> R
interval : (R, R) -> %
interval : R -> %
interval : Fraction Integer -> %
negative? : % -> Boolean
positive? : % -> Boolean
qinterval : (R, R) -> %
sup : % -> R
width : % -> R
```

These exports come from (p1190) `GcdDomain()`:

```

0 : () -> %
1 : () -> %
associates? : (%,% ) -> Boolean
characteristic : () -> NonNegativeInteger
coerce : % -> %
coerce : Integer -> %
coerce : % -> OutputForm
exquo : (%,% ) -> Union(%, "failed")
gcd : (%,% ) -> %
gcd : List % -> %
gcdPolynomial :
  (SparseUnivariatePolynomial %,
   SparseUnivariatePolynomial %) ->
  SparseUnivariatePolynomial %
hash : % -> SingleInteger
latex : % -> String
lcm : List % -> %
lcm : (%,% ) -> %
one? : % -> Boolean

PrincipalIdealDomain examples

---

The category of constructive principal ideal domains, i.e. where a single generator can be constructively found for any ideal given by a finite set of generators. Note that this constructive definition only implies that finitely generated ideals are principal. It is not clear what we would mean by an infinitely generated ideal.

See Also:

o )show PrincipalIdealDomain

---

**See:**

Unique Factorization Domains are a subset of Principal Ideal Domains.

⇐ “UniqueFactorizationDomain” (UFD) 14 on page 1234 Principal Ideal Domains are a subset of Euclidean Domains.

⇒ “EuclideanDomain” (EUCDOM) 15 on page 1247

⇐ “GcdDomain” (GCDDOM) 13 on page 1190

**Exports:**

0	1	associates?	characteristic	coerce
expressIdealMember	exquo	gcd	gcdPolynomial	hash
latex	lcm	one?	principalIdeal	recip
sample	subtractIfCan	unit?	unitCanonical	unitNormal
zero?	?+?	?-?	-?	?=?
?~=?	?*?	?**?	?^?	

**Attributes exported:**

- **noZeroDivisors** is true if  $x * y \neq 0$  implies both  $x$  and  $y$  are non-zero.
- **commutative**(“\*”) is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation **recip** can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .

These are directly exported but not implemented:

```
expressIdealMember : (List %,%) -> Union(List %,"failed")
principalIdeal : List % -> Record(coef: List %,generator: %)
```

These exports come from (p1190) GcdDomain():

)abbrev category PID PrincipalIdealDomain
++ Description:
++ The category of constructive principal ideal domains, i.e.
++ where a single generator can be constructively found for
++ any ideal given by a finite set of generators.
++ Note that this constructive definition only implies that
++ finitely generated ideals are principal. It is not clear
++ what we would mean by an infinitely generated ideal.

PrincipalIdealDomain(): Category == GcdDomain with
  principalIdeal: List % -> Record(coef:List %,generator:%)
  ++ principalIdeal([f1,...,fn]) returns a record whose
  ++ generator component is a generator of the ideal
  ++ generated by \spad{[f1,...,fn]} whose coef component satisfies
  ++ \spad{generator = sum (input.i * coef.i)}
  expressIdealMember: (List %,%) -> Union(List %, "failed")
  ++ expressIdealMember([f1,...,fn],h) returns a representation
  ++ of h as a linear combination of the fi or "failed" if h
  ++ is not in the ideal generated by the fi.

— category DIVCAT DivisorCategory —

```

)abbrev category DIVCAT DivisorCategory
++ Authors: Gaetan Hache
++ Date Created: may 1997
++ Date Last Updated: April 2010, by Tim Daly
++ Description: This category exports the function for domains
DivisorCategory(S:SetCategory):Category == Exports where

INT      ==> Integer
BOOLEAN ==> Boolean
LIST     ==> List

Exports ==> _
  Join(AbelianGroup,Module Integer,FreeAbelianMonoidCategory(S,Integer)) with

  degree: % -> INT
    ++ degree(d) returns the degree of the divisor d

  split: % -> List %
    ++ split(d) splits the divisor d. For example,
    ++ split( 2 p1 + 3p2 ) returns the list [ 2 p1, 3 p2 ].

  "<=" : (%,%) -> BOOLEAN

  collect: % -> %
    ++ collect collects the duplicative points in the divisor.

```

```

concat: (%,% ) -> %
  ++ concat(a,b) concats the divisor a and b
  ++ without collecting the duplicative points.

effective?: % -> BOOLEAN
  ++ effective?(d) returns true if d >= 0.

supp: % -> LIST(S)
  ++ supp(d) returns the support of the divisor d.

suppOfZero: % -> LIST(S)
  ++ suppOfZero(d) returns the elements of the support of d that
  ++ have a positive coefficient.

suppOfPole: % -> LIST(S)
  ++ suppOfZero(d) returns the elements of the support of d that
  ++ have a negative coefficient.

divOfZero: % -> %
  ++ divOfZero(d) returns the positive part of d.

divOfPole: % -> %
  ++ divOfPole(d) returns the negative part of d.

incr: % -> %

EuclideanDomain examples

---

A constructive euclidean domain, i.e. one can divide producing a quotient and a remainder where the remainder is either zero or is smaller (euclideanSize) than the divisor.

Conditional attributes:

```

multiplicativeValuation - Size(a*b)=Size(a)*Size(b)
additiveValuation      - Size(a*b)=Size(a)+Size(b)

```

Principal Ideal Domains are a subset of Euclidean Domains.  
Euclidean Domains are a subset of Fields.

See Also:

```
o )show EuclideanDomain
```

---

← “PrincipalIdealDomain” (PID) [14](#) on page [1228](#).

⇒ “Field” (FIELD) [16](#) on page [1283](#)

**See:**

⇒ “Field” (FIELD) [16](#) on page [1283](#)

⇒ “IntegerNumberSystem” (INS) [16](#) on page [1290](#)

⇒ “PAdicIntegerCategory” (PADICCT) [16](#) on page [1311](#)

⇒ “QuotientFieldCategory” (QFCAT) [17](#) on page [1440](#)

← “PrincipalIdealDomain” (PID) [14](#) on page [1228](#)

**Exports:**

1	0	associates?	characteristic	coerce
divide	euclideanSize	expressIdealMember	exquo	extendedEuclidean
gcd	gcdPolynomial	hash	latex	lcm
multiEuclidean	one?	principalIdeal	recip	sample
sizeLess?	subtractIfCan	unit?	unitCanonical	unitNormal
zero?	?+?	?-?	-?	?=?
?quo?	?rem?	?~=?	?*?	?**?
?^?				

**Attributes exported:**

- **noZeroDivisors** is true if  $x * y \neq 0$  implies both  $x$  and  $y$  are non-zero.
- **commutative(“\*”)** is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation **recip** can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .

These are directly exported but not implemented:

```

divide : (%,%) -> Record(quotient: %,remainder: %)
euclideanSize : % -> NonNegativeInteger

```

These are implemented by this category:

```

expressIdealMember : (List %,%) -> Union(List %,"failed")
exquo : (%,%) -> Union(%,"failed")
extendedEuclidean : (%,%) -> Record(coef1: %,coef2: %,generator: %)
extendedEuclidean : (%,%,%) -> Union(Record(coef1: %,coef2: %),"failed")
gcd : (%,%) -> %
multiEuclidean : (List %,%) -> Union(List %,"failed")
principalIdeal : List % -> Record(coef: List %,generator: %)
sizeLess? : (%,%) -> Boolean
?quo? : (%,%) -> %
?rem? : (%,%) -> %

```

These exports come from (p1228) `PrincipalIdealDomain()`:

```

0 : () -> %

?^? : (% , NonNegativeInteger) -> %

```

— category EUCDOM EuclideanDomain —

```

)abbrev category EUCDOM EuclideanDomain
++ Description:
++ A constructive euclidean domain, i.e. one can divide producing
++ a quotient and a remainder where the remainder is either zero
++ or is smaller ( $\backslash\text{spadfun}\{\text{euclideanSize}\}$ ) than the divisor.
++
++ Conditional attributes\br
++  $\backslash\text{tab}\{5\}\text{multiplicativeValuation}\backslash\text{tab}\{5\}\text{Size}(a*b)=\text{Size}(a)*\text{Size}(b)\backslash\text{br}$ 
++  $\backslash\text{tab}\{5\}\text{additiveValuation}\backslash\text{tab}\{11\}\text{Size}(a*b)=\text{Size}(a)+\text{Size}(b)$ 

EuclideanDomain(): Category == PrincipalIdealDomain with
sizeLess?: (% , %) -> Boolean
++ sizeLess?(x,y) tests whether x is strictly
++ smaller than y with respect to the
++  $\backslash\text{spadfunFrom}\{\text{euclideanSize}\}\{\text{EuclideanDomain}\}$ .
euclideanSize: % -> NonNegativeInteger
++ euclideanSize(x) returns the euclidean size of the element x.
++ Error: if x is zero.
divide: (% , %) -> Record(quotient:% , remainder:%)
++ divide(x,y) divides x by y producing a record containing a
++  $\backslash\text{spad}\{\text{quotient}\}$  and  $\backslash\text{spad}\{\text{remainder}\}$ ,
++ where the remainder is smaller (see
++  $\backslash\text{spadfunFrom}\{\text{sizeLess?}\}\{\text{EuclideanDomain}\}$ ) than the divisor y.
"quo" : (% , %) -> %
++ x quo y is the same as  $\backslash\text{spad}\{\text{divide}(x,y).\text{quotient}\}$ .
++ See  $\backslash\text{spadfunFrom}\{\text{divide}\}\{\text{EuclideanDomain}\}$ .
"rem" : (% , %) -> %
++ x rem y is the same as  $\backslash\text{spad}\{\text{divide}(x,y).\text{remainder}\}$ .
++ See  $\backslash\text{spadfunFrom}\{\text{divide}\}\{\text{EuclideanDomain}\}$ .
extendedEuclidean: (% , %) -> Record(coef1:% , coef2:% , generator:%)
-- formerly called princIdeal
++ extendedEuclidean(x,y) returns a record rec where
++  $\backslash\text{spad}\{\text{rec.coef1}*x+\text{rec.coef2}*y = \text{rec.generator}\}$  and
++ rec.generator is a gcd of x and y.
++ The gcd is unique only
++ up to associates if  $\backslash\text{spadatt}\{\text{canonicalUnitNormal}\}$  is not asserted.
++  $\backslash\text{spadfun}\{\text{principalIdeal}\}$  provides a version of this operation
++ which accepts an arbitrary length list of arguments.
extendedEuclidean: (% , % , %) -> Union(Record(coef1:% , coef2:%) , "failed")
-- formerly called expressIdealElt
++ extendedEuclidean(x,y,z) either returns a record rec
++ where  $\backslash\text{spad}\{\text{rec.coef1}*x+\text{rec.coef2}*y=z\}$  or returns "failed"

```

```

++ if z cannot be expressed as a linear combination of x and y.
multiEuclidean: (List %,%) -> Union(List %,"failed")
++ multiEuclidean([f1,...,fn],z) returns a list of coefficients
++ \spad{[a1, ..., an]} such that
++ \spad{ z / prod fi = sum aj/fj}.
++ If no such list of coefficients exists, "failed" is returned.

=====
UnivariatePowerSeriesCategory examples
=====

```

UnivariatePowerSeriesCategory is the most general univariate power series category with exponents in an ordered abelian monoid. Note that this category exports a substitution function if it is possible to multiply exponents. Also note that this category exports a derivative operation if it is possible to multiply coefficients by exponents.

### Attributes Exported:

- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation **recip** can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all x.
- **rightUnitary** is true if  $x * 1 = x$  for all x.
- if #1 has IntegralDomain then noZeroDivisors where **noZeroDivisors** is true if  $x * y \neq 0$  implies both x and y are non-zero.
- if #1 has CommutativeRing then commutative(“\*”) where **commutative**(“\*”) is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.

These are directly exported but not implemented:

```

approximate : (% , Expon) -> Coef
  if Coef has **: (Coef , Expon) -> Coef

++ Date Created: 21 December 1989
++ Date Last Updated: 20 September 1993
++ Description:
++ \spadtype{UnivariatePowerSeriesCategory} is the most general
++ univariate power series category with exponents in an ordered
++ abelian monoid.
++ Note that this category exports a substitution function if it is
++ possible to multiply exponents.
++ Also note that this category exports a derivative operation if it is
++ possible to multiply coefficients by exponents.

UnivariatePowerSeriesCategory(Coef,Expon): Category == Definition where
  Coef   : Ring
  Expon  : OrderedAbelianMonoid
  Term ==> Record(k:Expon,c:Coef)

Definition ==> PowerSeriesCategory(Coef,Expon,SingletonAsOrderedSet) with

terms: % -> Stream Term
  ++ \spad{terms(f(x))} returns a stream of non-zero terms, where a
  ++ a term is an exponent-coefficient pair. The terms in the stream
  ++ are ordered by increasing order of exponents.
--series: Stream Term -> %
  ---++ \spad{series(st)} creates a series from a stream of non-zero terms,
  ---++ where a term is an exponent-coefficient pair. The terms in the
  ---++ stream should be ordered by increasing order of exponents.
elt: (% ,Expon) -> Coef
  ++ \spad{elt(f(x),r)} returns the coefficient of the term of degree r in
  ++ \spad{f(x)}. This is the same as the function \spadfun{coefficient}.
variable: % -> Symbol
  ++ \spad{variable(f)} returns the (unique) power series variable of
  ++ the power series f.
center: % -> Coef
  ++ \spad{center(f)} returns the point about which the series f is
  ++ expanded.
multiplyExponents: (% ,PositiveInteger) -> %
  ++ \spad{multiplyExponents(f,n)} multiplies all exponents of the power
  ++ series f by the positive integer n.
order: % -> Expon
  ++ \spad{order(f)} is the degree of the lowest order non-zero term in f.
  ++ This will result in an infinite loop if f has no non-zero terms.
order: (% ,Expon) -> Expon
  ++ \spad{order(f,n) = min(m,n)}, where m is the degree of the
  ++ lowest order non-zero term in f.
truncate: (% ,Expon) -> %
  ++ \spad{truncate(f,k)} returns a (finite) power series consisting of
  ++ the sum of all terms of f of degree \spad{<= k}.
truncate: (% ,Expon,Expon) -> %
  ++ \spad{truncate(f,k1,k2)} returns a (finite) power
  ++ series consisting of

```

```

++ the sum of all terms of f of degree d with \spad{k1 <= d <= k2}.
if Coef has coerce: Symbol -> Coef then
  if Coef has "**":(Coef,Expon) -> Coef then
    approximate: (% ,Expon) -> Coef
      ++ \spad{approximate(f)} returns a truncated power series with the
      ++ series variable viewed as an element of the coefficient domain.
extend: (% ,Expon) -> %
  ++ \spad{extend(f,n)} causes all terms of f of degree <= n
  ++ to be computed.
if Expon has SemiGroup then Eltable(% ,%)
if Coef has "*": (Expon,Coef) -> Coef then
  DifferentialRing
  --!! DifferentialExtension Coef
  if Coef has PartialDifferentialRing Symbol then
    PartialDifferentialRing Symbol
if Coef has "**": (Coef,Expon) -> Coef then
  eval: (% ,Coef) -> Stream Coef
    ++ \spad{eval(f,a)} evaluates a power series at a value in the
    ++ ground ring by returning a stream of partial sums.

zero?	?*?	?**?	?+?
?-?	-?	?<?	?<=?
?=?	?>?	?>=?	?^?
?~=?	?quo?	?rem?	

**Attributes Exported:**

- **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is `associates?(a,b)` returns true if and only if `unitCanonical(a) = unitCanonical(b)`.
- **multiplicativeValuation** implies `euclideanSize(a*b)=euclideanSize(a)*euclideanSize(b)`.
- **noZeroDivisors** is true if  $x * y \neq 0$  implies both  $x$  and  $y$  are non-zero.
- **commutative(“\*”)** is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has `unitsKnown` means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .

These are directly exported but not implemented:

```
addmod : (%,%,%) -> %
base : () -> %
dec : % -> %
hash : % -> %
```

```

inc : % -> %

  p : Integer
  I ==> Integer
  NNI ==> NonNegativeInteger
  ST ==> Stream
  SUP ==> SparseUnivariatePolynomial

Definition ==> Join(EuclideanDomain,CharacteristicZero) with
  digits: % -> ST I
  ++ \spad{digits(x)} returns a stream of p-adic digits of x.
  order: % -> NNI
  ++ \spad{order(x)} returns the exponent of the highest power of p
  ++ dividing x.
  extend: (% ,I) -> %
  ++ \spad{extend(x,n)} forces the computation of digits up to order n.
  complete: % -> %
  ++ \spad{complete(x)} forces the computation of all digits.
  modulus: () -> I
  ++ \spad{modulus()} returns the value of p.
  moduloP: % -> I
  ++ \spad{modulo(x)} returns a, where \spad{x = a + b p}.
  quotientByP: % -> %
  ++ \spad{quotientByP(x)} returns b, where \spad{x = a + b p}.
  approximate: (% ,I) -> I

```

```

++ \spad{approximate(x,n)} returns an integer y such that
++ \spad{y = x (mod p^n)}
++ when n is positive, and 0 otherwise.
sqrt: (% ,I) -> %
++ \spad{sqrt(b,a)} returns a square root of b.
++ Argument \spad{a} is a square root of b \spad{(mod p)}.
root: (SUP I,I) -> %
++ \spad{root(f,a)} returns a root of the polynomial \spad{f}.
++ Argument \spad{a} must be a root of \spad{f} \spad{(mod p)}.

?>?	?>=?	

### Attributes Exported:

-

- if  $R$  has `canonicalUnitNormal` then `canonicalUnitNormal` where **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is `associates?(a,b)` returns true if and only if `unitCanonical(a) = unitCanonical(b)`.
- if  $\$$  has `IntegralDomain` then `noZeroDivisors` where **noZeroDivisors** is true if  $x*y \neq 0$  implies both  $x$  and  $y$  are non-zero.
- if  $\$$  has `CommutativeRing` then `commutative(“*”)` where **commutative(“\*”)**  is true if it has an operation  $“*” : (D, D) \rightarrow D$  which is commutative.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has `unitsKnown` means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .

These are directly exported but not implemented:

— category POLYCAT PolynomialCategory —

```

)abbrev category POLYCAT PolynomialCategory
++ Description:
++ The category for general multi-variate polynomials over a ring
++ R, in variables from VarSet, with exponents from the
++ \spadtype{OrderedAbelianMonoidSup}.

PolynomialCategory(R:Ring, E:OrderedAbelianMonoidSup, VarSet:OrderedSet):
  Category ==
Join(PartialDifferentialRing VarSet, FiniteAbelianMonoidRing(R, E),
  Evalable %, InnerEvalable(VarSet, R),
  InnerEvalable(VarSet, %), RetractableTo VarSet,
  FullyLinearlyExplicitRingOver R) with
degree : (% ,VarSet) -> NonNegativeInteger
  ++ degree(p,v) gives the degree of polynomial p with respect
  ++ to the variable v.
degree : (% ,List(VarSet)) -> List(NonNegativeInteger)
  ++ degree(p,lv) gives the list of degrees of polynomial p
  ++ with respect to each of the variables in the list lv.
coefficient: (% ,VarSet,NonNegativeInteger) -> %
  ++ coefficient(p,v,n) views the polynomial p as a univariate
  ++ polynomial in v and returns the coefficient of the \spad{v**n} term.
coefficient: (% ,List VarSet,List NonNegativeInteger) -> %
  ++ coefficient(p, lv, ln) views the polynomial p as a polynomial
  ++ in the variables of lv and returns the coefficient of the term
  ++ \spad{lv**ln}, i.e. \spad{prod(lv_i ** ln_i)}.
monomials: % -> List %
  ++ monomials(p) returns the list of non-zero monomials of
  ++ polynomial p, i.e.
  ++ \spad{monomials(sum(a_(i) X^(i))) = [a_(1) X^(1),...,a_(n) X^(n)]}.
univariate : (% ,VarSet) -> SparseUnivariatePolynomial(%)
  ++ univariate(p,v) converts the multivariate polynomial p
  ++ into a univariate polynomial in v, whose coefficients are still
  ++ multivariate polynomials (in all the other variables).
univariate : % -> SparseUnivariatePolynomial(R)
  ++ univariate(p) converts the multivariate polynomial p,
  ++ which should actually involve only one variable,
  ++ into a univariate polynomial
  ++ in that variable, whose coefficients are in the ground ring.
  ++ Error: if polynomial is genuinely multivariate
mainVariable : % -> Union(VarSet,"failed")
  ++ mainVariable(p) returns the biggest variable which actually
  ++ occurs in the polynomial p, or "failed" if no variables are
  ++ present.
  ++ fails precisely if polynomial satisfies ground?
minimumDegree : (% ,VarSet) -> NonNegativeInteger
  ++ minimumDegree(p,v) gives the minimum degree of polynomial p
  ++ with respect to v, i.e. viewed a univariate polynomial in v

```

```

minimumDegree : (% , List(VarSet)) -> List(NonNegativeInteger)
  ++ minimumDegree(p, lv) gives the list of minimum degrees of the
  ++ polynomial p with respect to each of the variables in the list lv
monicDivide : (% , % , VarSet) -> Record(quotient:% , remainder:%)
  ++ monicDivide(a,b,v) divides the polynomial a by the polynomial b,
  ++ with each viewed as a univariate polynomial in v returning
  ++ both the quotient and remainder.
  ++ Error: if b is not monic with respect to v.
monomial : (% , VarSet, NonNegativeInteger) -> %
  ++ monomial(a,x,n) creates the monomial \spad{a*x**n} where \spad{a} is
  ++ a polynomial, x is a variable and n is a nonnegative integer.
monomial : (% , List VarSet, List NonNegativeInteger) -> %
  ++ monomial(a, [v1..vn], [e1..en]) returns \spad{a*prod(vi**ei)}.

tan	tanh	terms	truncate
unit?	unitCanonical	unitNormal	variable
variables	zero?	?*?	?**?
?+?	?-?	-?	?=?
?^?	?~=?	?/?	?..?

**Attributes Exported:**

- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has `unitsKnown` means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .
- if `#1` has `IntegralDomain` then `noZeroDivisors` where **noZeroDivisors** is true if  $x * y \neq 0$  implies both  $x$  and  $y$  are non-zero.
- if `#1` has `CommutativeRing` then `commutative(“*”)`  where **commutative(“\*”)**  is true if it has an operation “ \* ” :  $(D, D) \rightarrow D$  which is commutative.

These are directly exported but not implemented:

```

coefficients : % -> Stream Coef
integrate : (% , Symbol) -> %
  if Coef has ACFS INT
  and Coef has PRIMCAT
  and Coef has TRANFUN
  and Coef has ALGEBRA FRAC INT
  or Coef has variables: Coef -> List Symbol
  and Coef has integrate: (Coef, Symbol) -> Coef
  and Coef has ALGEBRA FRAC INT
integrate : % -> % if Coef has ALGEBRA FRAC INT

```

```

— category UTSCAT UnivariateTaylorSeriesCategory —

```
)abbrev category UTSCAT UnivariateTaylorSeriesCategory
++ Author: Clifton J. Williamson
++ Date Created: 21 December 1989
++ Date Last Updated: 26 May 1994
++ Description:
++ \spadtype{UnivariateTaylorSeriesCategory} is the category of Taylor
++ series in one variable.

UnivariateTaylorSeriesCategory(Coef): Category == Definition where
  Coef : Ring
  I    ==> Integer
  L    ==> List
  NNI  ==> NonNegativeInteger
  OUT  ==> OutputForm
  RN   ==> Fraction Integer
  STTA ==> StreamTaylorSeriesOperations Coef
  STTF ==> StreamTranscendentalFunctions Coef
  STNC ==> StreamTranscendentalFunctionsNonCommutative Coef
  Term ==> Record(k:NNI,c:Coef)

Definition ==> UnivariatePowerSeriesCategory(Coef,NNI) with

series: Stream Term -> %
  ++ \spad{series(st)} creates a series from a stream of non-zero terms,
  ++ where a term is an exponent-coefficient pair. The terms in the
  ++ stream should be ordered by increasing order of exponents.
coefficients: % -> Stream Coef
  ++ \spad{coefficients(a0 + a1 x + a2 x**2 + ...)} returns a stream
  ++ of coefficients: \spad{[a0,a1,a2,...]}. The entries of the stream
  ++ may be zero.
series: Stream Coef -> %
  ++ \spad{series([a0,a1,a2,...])} is the Taylor series
  ++ \spad{a0 + a1 x + a2 x**2 + ...}.
quoByVar: % -> %
  ++ \spad{quoByVar(a0 + a1 x + a2 x**2 + ...)}
  ++ returns \spad{a1 + a2 x + a3 x**2 + ...}
  ++ Thus, this function subtracts the constant term and divides by
  ++ the series variable. This function is used when Laurent series
  ++ are represented by a Taylor series and an order.
multiplyCoefficients: (I -> Coef,% ) -> %
  ++ \spad{multiplyCoefficients(f,sum(n = 0..infinity,a[n] * x**n))}
  ++ returns \spad{sum(n = 0..infinity,f(n) * a[n] * x**n)}.
  ++ This function is used when Laurent series are represented by
  ++ a Taylor series and an order.
polynomial: (% ,NNI) -> Polynomial Coef
```

```

++ \spad{polynomial(f,k)} returns a polynomial consisting of the sum
++ of all terms of f of degree \spad{<= k}.
polynomial: (% ,NNI,NNI) -> Polynomial Coef
++ \spad{polynomial(f,k1,k2)} returns a polynomial consisting of the
++ sum of all terms of f of degree d with \spad{k1 <= d <= k2}.

if Coef has Field then
  "**": (% ,Coef) -> %
  ++ \spad{f(x) ** a} computes a power of a power series.
  ++ When the coefficient ring is a field, we may raise a series
  ++ to an exponent from the coefficient ring provided that the
  ++ constant coefficient of the series is 1.

if Coef has Algebra Fraction Integer then
  integrate: % -> %
  ++ \spad{integrate(f(x))} returns an anti-derivative of the power
  ++ series \spad{f(x)} with constant coefficient 0.
  ++ We may integrate a series when we can divide coefficients
  ++ by integers.
  if Coef has integrate: (Coef,Symbol) -> Coef and _
    Coef has variables: Coef -> List Symbol then
      integrate: (% ,Symbol) -> %
      ++ \spad{integrate(f(x),y)} returns an anti-derivative of the
      ++ power series \spad{f(x)} with respect to the variable \spad{y}.
  if Coef has TranscendentalFunctionCategory and _
    Coef has PrimitiveFunctionCategory and _
    Coef has AlgebraicallyClosedFunctionSpace Integer then
      integrate: (% ,Symbol) -> %
      ++ \spad{integrate(f(x),y)} returns an anti-derivative of
      ++ the power series \spad{f(x)} with respect to the variable
      ++ \spad{y}.
  RadicalCategory
  --++ We provide rational powers when we can divide coefficients
  --++ by integers.
  TranscendentalFunctionCategory
  --++ We provide transcendental functions when we can divide
  --++ coefficients by integers.

=====
AlgebraicallyClosedField examples
=====

```

This category is a model for algebraically closed fields.

Given the polynomial:

```
pi:Polynomial(Integer):=-3*x^3+2*x+13
      3
      - 3x  + 2x + 13
```

```
rootOf(pi)
      x
```

```
rootsOf(pi)
[%x0,%x1,- %x1 - %x0]
```

```
zeroOf(pi)
      x
```

```
zerosOf(pi)
      +-----+           +-----+
      |      2           |      2
      - \|- 27%x3 + 24 - 3%x3 \|- 27%x3 + 24 - 3%x3
[%x3,-----,-----]
              6              6
```

These functions can also be applied to Sparse Univariate Polynomials:

```
sup:SparseUnivariatePolynomial(Integer):=-3*x^3+2*x+13
      3
      - 3? + 2? + 13
```

```
rootOf(sup)
      %B
```

```
rootOf(sup,x)
      x
```

```
rootsOf(sup)
[%%C0,%%C1,- %%C1 - %%C0]
```

```
rootsOf(sup,x)
```

```
[%x6,%x7,- %x7 - %x6]
```

```
zeroOf(sup)
%D
```

```
zeroOf(sup,x)
x
```

```
zerosOf(sup)
```

$$\left[ \frac{-\sqrt{-27\%E0 + 24} - 3\%E0}{6}, \frac{-\sqrt{-27\%E0 + 24} - 3\%E0}{6} \right]$$

```
zerosOf(sup,x)
```

$$\left[ \frac{-\sqrt{-27\%x9 + 24} - 3\%x9}{6}, \frac{-\sqrt{-27\%x9 + 24} - 3\%x9}{6} \right]$$

⇐ “RadicalCategory” (RADCAT) [2](#) on page [99](#)

**Exports:**

0	1	associates?	characteristic
coerce	divide	euclideanSize	expressIdealMember
exquo	extendedEuclidean	factor	gcd
gcdPolynomial	hash	inv	latex
lcm	multiEuclidean	nthRoot	one?
prime?	principalIdeal	recip	rootOf
rootsOf	sample	sizeLess?	sqrt
squareFree	squareFreePart	subtractIfCan	unit?
unitCanonical	unitNormal	zero?	zeroOf
zerosOf	?*?	?**?	?+?
?-?	-?	?/?	?=?
?quo?	?rem?	?^=?	?^?

**Attributes Exported:**

- **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is `associates?(a,b)` returns true if and only if `unitCanonical(a) = unitCanonical(b)`.
- **canonicalsClosed** is true if `unitCanonical(a)*unitCanonical(b) = unitCanonical(a*b)`.
- **noZeroDivisors** is true if  $x * y \neq 0$  implies both  $x$  and  $y$  are non-zero.
- **commutative(“\*”)** is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has `unitsKnown` means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .

These are directly exported but not implemented:

```
rootOf : Polynomial % -> %
```

These are implemented by this category:

```
rootOf : SparseUnivariatePolynomial % -> %
rootOf : (SparseUnivariatePolynomial %,Symbol) -> %
rootsOf : Polynomial % -> List %
rootsOf : (SparseUnivariatePolynomial %,Symbol) -> List %
rootsOf : SparseUnivariatePolynomial % -> List %
zeroOf : (SparseUnivariatePolynomial %,Symbol) -> %
zeroOf : Polynomial % -> %
zeroOf : SparseUnivariatePolynomial % -> %
zerosOf : Polynomial % -> List %
zerosOf : (SparseUnivariatePolynomial %,Symbol) -> List %
zerosOf : SparseUnivariatePolynomial % -> List %
```

These exports come from (p1283) Field():

```

=====
DifferentialPolynomialCategory examples
=====
```

DifferentialPolynomialCategory is a category constructor specifying basic functions in an ordinary differential polynomial ring with a given ordered set of differential indeterminates. In addition, it implements defaults for the basic functions.

The functions order and weight are extended from the set of derivatives of differential indeterminates to the set of differential polynomials. Other operations provided on differential polynomials are leader, initial, separant, differentialVariables, and isobaric?. Furthermore, if the ground ring is a differential ring, then evaluation (substitution of differential indeterminates by elements of the ground ring or by differential polynomials) is provided by eval.

A convenient way of referencing derivatives is provided by the functions makeVariable.

To construct a domain using this constructor, one needs to provide a ground ring R, an ordered set S of differential indeterminates, a ranking V on the set of derivatives of the differential indeterminates, and a set E of exponents in bijection with the set of differential monomials in the given differential indeterminates.

**Attributes Exported:**

- 
- if  $R$  has `unitNormal` then `canonicalUnitNormal` where **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is `associates?(a,b)` returns true if and only if `unitCanonical(a) = unitCanonical(b)`.
- if  $R$  has `IntegralDomain` then `noZeroDivisors` where **noZeroDivisors** is true if  $x*y \neq 0$  implies both  $x$  and  $y$  are non-zero.
- if  $R$  has `CommutativeRing` then `commutative(“*”)`  where **commutative(“\*”)**  is true if it has an operation  $*$  :  $(D, D) \rightarrow D$  which is commutative.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has `unitsKnown` means that the operation `recip` can only return “failed” if its argument is not a unit.

- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .

These are implemented by this category:

  -- Examples:
```

```

-- s:=makeVariable('s)
-- p:= 3*(s 1)**2 + s*(s 2)**3
-- all functions below have default implementations
-- using primitives from V

makeVariable: S -> (NonNegativeInteger -> $)
  ++ makeVariable(s) views s as a differential
  ++ indeterminate, in such a way that the n-th
  ++ derivative of s may be simply referenced as z.n
  ++ where z :=makeVariable(s).
  ++ Note that In the interpreter, z is
  ++ given as an internal map, which may be ignored.
  -- Example: makeVariable('s); %.5

differentialVariables: $ -> List S
  ++ differentialVariables(p) returns a list of differential
  ++ indeterminates occurring in a differential polynomial p.
order : ($, S) -> NonNegativeInteger
  ++ order(p,s) returns the order of the differential
  ++ polynomial p in differential indeterminate s.
order : $ -> NonNegativeInteger
  ++ order(p) returns the order of the differential polynomial p,
  ++ which is the maximum number of differentiations of a
  ++ differential indeterminate, among all those appearing in p.
degree: ($, S) -> NonNegativeInteger
  ++ degree(p, s) returns the maximum degree of
  ++ the differential polynomial p viewed as a differential polynomial
  ++ in the differential indeterminate s alone.
weights: $ -> List NonNegativeInteger
  ++ weights(p) returns a list of weights of differential monomials
  ++ appearing in differential polynomial p.
weight: $ -> NonNegativeInteger
  ++ weight(p) returns the maximum weight of all differential monomials
  ++ appearing in the differential polynomial p.
weights: ($, S) -> List NonNegativeInteger
  ++ weights(p, s) returns a list of
  ++ weights of differential monomials
  ++ appearing in the differential polynomial p when p is viewed
  ++ as a differential polynomial in the differential indeterminate s
  ++ alone.
weight: ($, S) -> NonNegativeInteger
  ++ weight(p, s) returns the maximum weight of all differential
  ++ monomials appearing in the differential polynomial p
  ++ when p is viewed as a differential polynomial in
  ++ the differential indeterminate s alone.
isobaric?: $ -> Boolean
  ++ isobaric?(p) returns true if every differential monomial appearing
  ++ in the differential polynomial p has same weight,
  ++ and returns false otherwise.
leader: $ -> V

```

```

++ leader(p) returns the derivative of the highest rank
++ appearing in the differential polynomial p
++ Note that an error occurs if p is in the ground ring.
initial:$ -> $
++ initial(p) returns the
++ leading coefficient when the differential polynomial p
++ is written as a univariate polynomial in its leader.
separant:$ -> $
++ separant(p) returns the
++ partial derivative of the differential polynomial p
++ with respect to its leader.
if R has DifferentialRing then
  InnerEvalable(S, R)
  InnerEvalable(S, $)
  Evalable $
  makeVariable: $ -> (NonNegativeInteger -> $)
  ++ makeVariable(p) views p as an element of a differential
  ++ ring, in such a way that the n-th
  ++ derivative of p may be simply referenced as z.n
  ++ where z := makeVariable(p).
  ++ Note that In the interpreter, z is
  ++ given as an internal map, which may be ignored.
  -- Example: makeVariable(p); %.5; makeVariable(%**2); %.2

=====
FieldOfPrimeCharacteristic examples
=====
```

FieldOfPrimeCharacteristic is the category of fields of prime characteristic, e.g. finite fields, algebraic closures of fields of prime characteristic, transcendental extensions of fields of prime characteristic.

See Also:

o )show FieldOfPrimeCharacteristic

See:

⇒ “FiniteFieldCategory” (FFIELD) [18](#) on page [1584](#)  
 ⇐ “CharacteristicNonZero” (CHARNZ) [10](#) on page [897](#)  
 ⇐ “Field” (FIELD) [16](#) on page [1283](#)

**Exports:**

0	1	associates?	characteristic
charthRoot	coerce	discreteLog	divide
euclideanSize	expressIdealMember	exquo	extendedEuclidean
factor	gcd	gcdPolynomial	hash
inv	latex	lcm	multiEuclidean
one?	order	prime?	primeFrobenius
principalIdeal	recip	sample	sizeLess?
squareFree	squareFreePart	subtractIfCan	unit?
unitCanonical	unitNormal	zero?	?*?
?**?	?+?	?-?	-?
?/?	?=?	?^?	?rem?
?quo?	?~=?		

**Attributes Exported:**

- **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is `associates?(a,b)` returns true if and only if `unitCanonical(a) = unitCanonical(b)`.
- **canonicalsClosed** is true if `unitCanonical(a)*unitCanonical(b) = unitCanonical(a*b)`.
- **noZeroDivisors** is true if  $x * y \neq 0$  implies both  $x$  and  $y$  are non-zero.

- **commutative**("\*") is true if it has an operation " \* " :  $(D, D) \rightarrow D$  which is commutative.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation `recip` can only return "failed" if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .

These are directly exported but not implemented:

```
order : % -> OnePointCompletion PositiveInteger
discreteLog : (%,%) -> Union(NonNegativeInteger,"failed")
```

These are implemented by this category:

```
primeFrobenius : % -> %
primeFrobenius : (%,NonNegativeInteger) -> %
```

These exports come from (p1283) `Field()`:

)abbrev category FINRALG FiniteRankAlgebra
++ Author: Barry Trager
++ Description:
++ A FiniteRankAlgebra is an algebra over a commutative ring R which
++ is a free R-module of finite rank.

FiniteRankAlgebra(R:CommutativeRing, UP:UnivariatePolynomialCategory R):
Category == Algebra R with
rank          : () -> PositiveInteger
  ++ rank() returns the rank of the algebra.
regularRepresentation : (% , Vector %) -> Matrix R
  ++ regularRepresentation(a,basis) returns the matrix of the
  ++ linear map defined by left multiplication by \spad{a} with respect
  ++ to the basis \spad{basis}.
trace         : % -> R
  ++ trace(a) returns the trace of the regular representation
  ++ of \spad{a} with respect to any basis.
norm         : % -> R
  ++ norm(a) returns the determinant of the regular representation
  ++ of \spad{a} with respect to any basis.
coordinates   : (% , Vector %) -> Vector R
  ++ coordinates(a,basis) returns the coordinates of \spad{a} with
  ++ respect to the basis \spad{basis}.
coordinates   : (Vector %, Vector %) -> Matrix R
  ++ coordinates([v1,...,vm], basis) returns the coordinates of the
  ++ vi's with to the basis \spad{basis}. The coordinates of vi are
  ++ contained in the ith row of the matrix returned by this
  ++ function.
represents    : (Vector R, Vector %) -> %
  ++ represents([a1,..,an],[v1,..,vn]) returns \spad{a1*v1+...+an*vn}.
discriminant  : Vector % -> R
  ++ discriminant([v1,..,vn]) returns
  ++ \spad{determinant(traceMatrix([v1,..,vn]))}.
traceMatrix  : Vector % -> Matrix R
  ++ traceMatrix([v1,..,vn]) is the n-by-n matrix ( Tr(vi * vj) )
characteristicPolynomial: % -> UP
  ++ characteristicPolynomial(a) returns the characteristic
  ++ polynomial of the regular representation of \spad{a} with respect
  ++ to any basis.
if R has Field then minimalPolynomial : % -> UP
  ++ minimalPolynomial(a) returns the minimal polynomial of \spad{a}.
if R has CharacteristicZero then CharacteristicZero
if R has CharacteristicNonZero then CharacteristicNonZero

### Attributes Exported:

- if \$ has IntegralDomain then noZeroDivisors where **noZeroDivisors** is true if  $x*y \neq 0$  implies both x and y are non-zero.
- if \$ has IntegralDomain then canonicalUnitNormal where **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is **associates?(a,b)** returns true if and only if **unitCanonical(a) = unitCanonical(b)**.
- if \$ has IntegralDomain then canonicalsClosed where **canonicalsClosed** is true if **unitCanonical(a)\*unitCanonical(b) = unitCanonical(a\*b)**.
- if \$ has IntegralDomain then commutative(“\*”) where **commutative(“\*”)** is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- if \$ has Ring or Group then unitsKnown where **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation **recip** can only return “failed” if its argument is not a unit.
- if \$ has CommutativeRing then leftUnitary where **leftUnitary** is true if  $1 * x = x$  for all x.

- if \$ has CommutativeRing then rightUnitary where **rightUnitary** is true if  $x * 1 = x$  for all x.
- **nil**

  setsymbName_!: (% , Symbol) -> Symbol

  subMultV: % -> NonNegativeInteger

```

```

localParamV: % -> List PCS

symbNameV: % -> Symbol

pointV: % -> ProjPt
  ++ pointV returns the infinitely close point.

curveV: % -> BlUpRing
  ++ curveV(p) returns the defining polynomial of the strict transform
  ++ on which lies the corresponding infinitely close point.

localPointV: % -> AFP
  ++ localPointV returns the coordinates of the local infinitely
  ++ close point

multV:      % -> NonNegativeInteger
  ++ multV returns the multiplicity of the infinitely close point.

chartV:     % -> BLMET -- CHH
  ++ chartV is the chart of the infinitely close point. The first integer
  ++ correspond to variable defining the exceptional line, the last one
  ++ the affine neighborhood and the second one is the
  ++ remaining integer. For example [1,2,3] means that
  ++ Z=1, X=X and Y=XY. [2,3,1] means that X=1, Y=Y and Z=YZ.

excpDivV:   % -> DIVISOR
  ++ excpDivV returns the exceptional divisor of the infinitely close point.

actualExtensionV: % -> K

```
=====
PseudoAlgebraicClosureOfPerfectFieldCategory examples
=====
```

This category exports the function for domains which implement dynamic extension using the simple notion of tower extensions. A tower extension  $T$  of the ground field  $K$  is any sequence of field extensions

$(T : K_0, K_1, \dots, K_{i-1}, \dots, K_n)$  where  $K_0 = K$   
and for  
 $i = 1, 2, \dots, n$ ,  $K_i$  is an extension of  $K_{i-1}$  of degree  $> 1$   
and defined by an irreducible polynomial  $p(Z)$  in  $K_{i-1}$ .

Two towers  
 $(T_1 : K_{01}, K_{11}, \dots, K_{i1}, \dots, K_{n1})$   
and  
 $(T_2 : K_{02}, K_{12}, \dots, K_{i2}, \dots, K_{n2})$   
are said to be related if  
 $T_1 \leq T_2$  (or  $T_1 \geq T_2$ ),  
that is if  
 $K_{i1} = K_{i2}$  for  $i = 1, 2, \dots, n_1$  (or  $i = 1, 2, \dots, n_2$ ).

Any algebraic operations defined for several elements are only defined if all of the concerned elements are coming from a set of related tower extensions.

=====

RealClosedField examples

=====

RealClosedField provides common access functions for all real closed fields.  
It provides computations with generic real roots of polynomials.

See Also:

o )show RealClosedField

**Exports:**

0	1	abs	allRootsOf
approximate	associates?	characteristic	coerce
divide	euclideanSize	expressIdealMember	exquo
extendedEuclidean	factor	gcd	gcdPolynomial
hash	inv	latex	lcm
mainDefiningPolynomial	mainForm	mainValue	max
min	multiEuclidean	negative?	nthRoot
one?	positive?	prime?	principalIdeal
recip	rename	rename!	retract
retractIfCan	rootOf	sample	sign
sizeLess?	sqrt	squareFree	squareFreePart
subtractIfCan	unit?	unitCanonical	unitNormal
zero?	?*?	?**?	?+?
?-?	-?	?/?	?<?
?<=?	?=?	?>?	?>=?
?^?	?~=?	?quo?	?rem?

**Attributes Exported:**

- **noZeroDivisors** is true if  $x * y \neq 0$  implies both  $x$  and  $y$  are non-zero.
- **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is `associates?(a,b)` returns true if and only if `unitCanonical(a) = unitCanonical(b)`.
- **canonicalsClosed** is true if `unitCanonical(a)*unitCanonical(b) = unitCanonical(a*b)`.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has `unitsKnown` means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .
- **commutative(“\*”)** is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.

These are directly exported but not implemented:

```
allRootsOf : SparseUnivariatePolynomial % -> List %
approximate : (%,% ) -> Fraction Integer
mainDefiningPolynomial :
  % -> Union(SparseUnivariatePolynomial %, "failed")
mainForm : % -> Union(OutputForm, "failed")
mainValue : % -> Union(SparseUnivariatePolynomial %, "failed")
rename : (% , OutputForm) -> %
rename! : (% , OutputForm) -> %
```

These are implemented by this category:

```
allRootsOf : Polynomial Integer -> List %
allRootsOf : Polynomial Fraction Integer -> List %
allRootsOf : Polynomial % -> List %
allRootsOf : SparseUnivariatePolynomial Integer -> List %
allRootsOf : SparseUnivariatePolynomial Fraction Integer -> List %

)abbrev category RNS RealNumberSystem
++ Author: Michael Monagan and Stephen M. Watt
++ Date Created: January 1988
++ Description:
++ The real number system category is intended as a model for the real
++ numbers. The real numbers form an ordered normed field. Note that
++ we have purposely not included \spadtype{DifferentialRing} or
++ the elementary functions (see \spadtype{TranscendentalFunctionCategory})
++ in the definition.

RealNumberSystem(): Category ==
  Join(Field, OrderedRing, RealConstant, RetractableTo Integer,
    RetractableTo Fraction Integer, RadicalCategory,
    ConvertibleTo Pattern Float, PatternMatchable Float,
    CharacteristicZero) with
  norm : % -> %
    ++ norm x returns the same as absolute value.
  ceiling : % -> %
    ++ ceiling x returns the small integer \spad{>= x}.
  floor: % -> %
    ++ floor x returns the largest integer \spad{<= x}.
  wholePart : % -> Integer
    ++ wholePart x returns the integer part of x.
  fractionPart : % -> %
    ++ fractionPart x returns the fractional part of x.
  truncate: % -> %
    ++ truncate x returns the integer between x and 0 closest to x.
  round: % -> %
    ++ round x computes the integer closest to x.
  abs : % -> %
    ++ abs x returns the absolute value of x.

=====
RecursivePolynomialCategory examples
=====

```

A category for general multi-variate polynomials with coefficients in a ring, variables in an ordered set, and exponents from an ordered abelian monoid, with a sup operation.

When not constant, such a polynomial is viewed as a univariate polynomial in its main variable w. r. t. to the total ordering on the elements in the ordered set, so that some operations usually defined for univariate polynomials make sense here.

**Attributes Exported:**

- if #1 has CommutativeRing then commutative(“\*”) where **commutative(“\*”)** is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- if #1 has IntegralDomain then noZeroDivisors where **noZeroDivisors** is true if  $x*y \neq 0$  implies both x and y are non-zero.
- if #1 has canonicalUnitNormal then canonicalUnitNormal where **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is **associates?(a,b)** returns true if and only if **unitCanonical(a) = unitCanonical(b)**.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation **recip** can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all x.
- **rightUnitary** is true if  $x * 1 = x$  for all x.

These are directly exported but not implemented:

```

variable	variables	zero?	?*?
?**?	?+?	?-? * -?	
?=?	?^?	?~=?	?/?
?..?	?quo?	?rem?	

**Attributes Exported:**

- if #1 has Field then canonicalUnitNormal where **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is `associates?(a,b)` returns true if and only if `unitCanonical(a) = unitCanonical(b)`.
- if #1 has Field then canonicalsClosed where **canonicalsClosed** is true if `unitCanonical(a)*unitCanonical(b) = unitCanonical(a*b)`.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .
- if #1 has IntegralDomain then noZeroDivisors where **noZeroDivisors** is true if  $x * y \neq 0$  implies both  $x$  and  $y$  are non-zero.
- if #1 has CommutativeRing then commutative(“\*”) where **commutative(“\*”)** is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.

These are directly exported but not implemented:

```

)abbrev category ULSCAT UnivariateLaurentSeriesCategory
++ Author: Clifton J. Williamson
++ Date Created: 21 December 1989
++ Date Last Updated: 20 September 1993
++ Description:
++ \spadtype{UnivariateLaurentSeriesCategory} is the category of
++ Laurent series in one variable.

UnivariateLaurentSeriesCategory(Coef): Category == Definition where
  Coef : Ring
  I ==> Integer
  NNI ==> NonNegativeInteger
  Term ==> Record(k:I,c:Coef)

Definition ==> UnivariatePowerSeriesCategory(Coef,Integer) with

series: Stream Term -> %
++ \spad{series(st)} creates a series from a stream of non-zero terms,
++ where a term is an exponent-coefficient pair. The terms in the
++ stream should be ordered by increasing order of exponents.

multiplyCoefficients: (I -> Coef,% ) -> %
++ \spad{multiplyCoefficients(f,sum(n = n0..infinity,a[n] * x**n)) =
++ sum(n = 0..infinity,f(n) * a[n] * x**n)}.
++ This function is used when Puiseux series are represented by
++ a Laurent series and an exponent.

if Coef has IntegralDomain then

rationalFunction: (% ,I) -> Fraction Polynomial Coef
++ \spad{rationalFunction(f,k)} returns a rational function
++ consisting of the sum of all terms of f of degree <= k.
++
++X w: SparseUnivariateLaurentSeries(Fraction(Integer), 'z,0):=0
++X rationalFunction(w,0)

rationalFunction: (% ,I,I) -> Fraction Polynomial Coef
++ \spad{rationalFunction(f,k1,k2)} returns a rational function
++ consisting of the sum of all terms of f of degree d with
++ \spad{k1 <= d <= k2}.

if Coef has Algebra Fraction Integer then

integrate: % -> %
++ \spad{integrate(f(x))} returns an anti-derivative of the power
++ series \spad{f(x)} with constant coefficient 1.
++ We may integrate a series when we can divide coefficients
++ by integers.

if Coef has integrate: (Coef,Symbol) -> Coef and _

```

```

Coef has variables: Coef -> List Symbol then

integrate: (% ,Symbol) -> %
  ++ \spad{integrate(f(x),y)} returns an anti-derivative of the power
  ++ series \spad{f(x)} with respect to the variable \spad{y}.

if Coef has TranscendentalFunctionCategory and _
  Coef has PrimitiveFunctionCategory and _
  Coef has AlgebraicallyClosedFunctionSpace Integer then

integrate: (% ,Symbol) -> %
  ++ \spad{integrate(f(x),y)} returns an anti-derivative of
  ++ the power series \spad{f(x)} with respect to the variable
  ++ \spad{y}.

RadicalCategory
--++ We provide rational powers when we can divide coefficients
--++ by integers.

TranscendentalFunctionCategory
--++ We provide transcendental functions when we can divide
--++ coefficients by integers.

if Coef has Field then Field
--++ Univariate Laurent series over a field form a field.
--++ In fact,  $K((x))$  is the quotient field of  $K[[x]]$ .

**Attributes Exported:**

- if #1 has Field then canonicalUnitNormal where **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is `associates?(a,b)` returns true if and only if `unitCanonical(a) = unitCanonical(b)`.
- if #1 has Field then canonicalsClosed where **canonicalsClosed** is true if `unitCanonical(a)*unitCanonical(b) = unitCanonical(a*b)`.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .
- if #1 has IntegralDomain then noZeroDivisors where **noZeroDivisors** is true if  $x*y \neq 0$  implies both  $x$  and  $y$  are non-zero.
- if #1 has CommutativeRing then commutative(“\*”) where **commutative(“\*”)** is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.

These are directly exported but not implemented:

**Attributes exported:**

- if \$ has `CommutativeRing` then `commutative(“*”)` where **commutative(“\*”)** is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- if \$ has `IntegralDomain` then `noZeroDivisors` where **noZeroDivisors** is true if  $x*y \neq 0$  implies both x and y are non-zero.
- if R has `Field` then `additiveValuation` where **additiveValuation** implies

`euclideanSize(a*b)=euclideanSize(a)+euclideanSize(b).`

- if `$` has `canonicalUnitNormal` then `canonicalUnitNormal` where **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is `associates?(a,b)` returns true if and only if `unitCanonical(a) = unitCanonical(b)`.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has `unitsKnown` means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .

These are directly exported but not implemented:

```
discriminant : % -> R if R has COMRING
divideExponents : (% , NonNegativeInteger) -> Union(%, "failed")

?=?	?>?	?>=?	?^?
?~=?	?quo?	?rem?	

**Attributes Exported:**

- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has `unitsKnown` means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .
- **noZeroDivisors** is true if  $x * y \neq 0$  implies both  $x$  and  $y$  are non-zero.
- **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is `associates?(a,b)` returns true if and only if `unitCanonical(a) = unitCanonical(b)`.
- **canonicalsClosed** is true if `unitCanonical(a)*unitCanonical(b) = unitCanonical(a*b)`.
- **commutative(“\*”)** is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- **nil**

These are implemented by this category:

ExtensionField F is the category of fields which extend the field F

See Also:

o )show ExtensionField

---

**See:**

⇒ “FiniteAlgebraicExtensionField” (FAXF) [19](#) on page [1649](#)

⇐ “Field” (FIELD) [16](#) on page [1283](#)

⇐ “RetractableTo” (RETRACT) [2](#) on page [102](#)

⇐ “VectorSpace” (VSPACE) [11](#) on page [1048](#)

**Exports:**

0	1	algebraic?	associates?
characteristic	charthRoot	coerce	degree
discreteLog	divide	euclideanSize	expressIdealMember
exquo	extendedEuclidean	extensionDegree	dimension
factor	Frobenius	gcd	gcdPolynomial
hash	inGroundField?	inv	latex
lcm	multiEuclidean	one?	order
prime?	primeFrbenius	principalIdeal	recip
retract	retractIfCan	sample	sizeLess?
squareFree	squareFreePart	subtractIfCan	transcendenceDegree
transcendent?	unit?	unitCanonical	unitNormal
zero?	?*?	?**?	?+?
?-?	-?	?/?	?=?
?^?	?quo?	?rem?	?~=?

### Attributes Exported:

- **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is `associates?(a,b)` returns true if and only if `unitCanonical(a) = unitCanonical(b)`.
- **canonicalsClosed** is true if `unitCanonical(a)*unitCanonical(b) = unitCanonical(a*b)`.
- **noZeroDivisors** is true if  $x * y \neq 0$  implies both  $x$  and  $y$  are non-zero.
- **commutative(“\*”)** is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has `unitsKnown` means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .

These are directly exported but not implemented:

```
inGroundField? : % -> Boolean
degree : % -> OnePointCompletion PositiveInteger
extensionDegree : () -> OnePointCompletion PositiveInteger
transcendenceDegree : () -> NonNegativeInteger
```

These are implemented by this category:

```
algebraic? : % -> Boolean
Frobenius : % -> % if F has FINITE
Frobenius : (% , NonNegativeInteger) -> % if F has FINITE
transcendent? : % -> Boolean
```

These exports come from (p1283) Field():

```

0 : () -> %
1 : () -> %
associates? : (%,% ) -> Boolean
characteristic : () -> NonNegativeInteger
coerce : % -> %
coerce : Integer -> %
coerce : % -> OutputForm
coerce : Fraction Integer -> %
divide : (%,% ) -> Record(quotient: %,remainder: %)
euclideanSize : % -> NonNegativeInteger

-?	?/?	?=?
?^?	?quo?	?rem?
?~=?		

**Attributes Exported:**

- **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is `associates?(a,b)` returns true if and only if `unitCanonical(a) = unitCanonical(b)`.
- **canonicalsClosed** is true if `unitCanonical(a)*unitCanonical(b) = unitCanonical(a*b)`.
- **noZeroDivisors** is true if  $x * y \neq 0$  implies both  $x$  and  $y$  are non-zero.
- **commutative(“\*”)** is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has `unitsKnown` means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .

These are directly exported but not implemented:

```

)abbrev category FFIELDC FiniteFieldCategory
++ Author: J. Grabmeier, A. Scheerhorn
++ Date Created: 11 March 1991
++ Date Last Updated: 31 March 1991
++ References:
++ D.Lipson, Elements of Algebra and Algebraic Computing, The
++ Benjamin/Cummings Publishing Company, Inc.-Menlo Park, California, 1981.
++ J. Grabmeier, A. Scheerhorn: Finite Fields in AXIOM.
++ AXIOM Technical Report Series, ATR/5 NP2522.
++ Description:
++ FiniteFieldCategory is the category of finite fields

FiniteFieldCategory() : Category ==_
Join(FieldOfPrimeCharacteristic,Finite,StepThrough,DifferentialRing) with
--      ,PolynomialFactorizationExplicit) with
charthRoot: $ -> $
++ charthRoot(a) takes the characteristic'th root of a.
++ Note that such a root is always defined in finite fields.
conditionP: Matrix $ -> Union(Vector $,"failed")
++ conditionP(mat), given a matrix representing a homogeneous system
++ of equations, returns a vector whose characteristic'th powers
++ is a non-trivial solution, or "failed" if no such vector exists.
-- the reason for implementing the following function is that we
-- can implement the functions order, getGenerator and primitive? on
-- category level without computing the, may be time intensive,
-- factorization of size()-1 at every function call again.
factorsOfCyclicGroupSize:_
() -> List Record(factor:Integer,exponent:Integer)
++ factorsOfCyclicGroupSize() returns the factorization of size()-1
-- the reason for implementing the function tableForDiscreteLogarithm
-- is that we can implement the functions discreteLog and
-- shanksDiscLogAlgorithm on category level
-- computing the necessary exponentiation tables in the respective
-- domains once and for all
-- absoluteDegree : $ -> PositiveInteger
-- ++ degree of minimal polynomial, if algebraic with respect
-- ++ to the prime subfield
tableForDiscreteLogarithm: Integer -> _
Table(PositiveInteger,NonNegativeInteger)
++ tableForDiscreteLogarithm(a,n) returns a table of the discrete
++ logarithms of \spad{a**0} up to \spad{a**(n-1)} which, called with
++ key \spad{lookup(a**i)} returns i for i in \spad{0..n-1}.
++ Error: if not called for prime divisors of order of
++      multiplicative group.
createPrimitiveElement: () -> $
++ createPrimitiveElement() computes a generator of the (cyclic)
++ multiplicative group of the field.
-- RDJ: Are these next lines to be included?
-- we run through the field and test, algorithms which construct
-- elements of larger order were found to be too slow

```

```

primitiveElement: () -> $
  ++ primitiveElement() returns a primitive element stored in a global
  ++ variable in the domain.
  ++ At first call, the primitive element is computed
  ++ by calling \spadfun{createPrimitiveElement}.
primitive?: $ -> Boolean
  ++ primitive?(b) tests whether the element b is a generator of the
  ++ (cyclic) multiplicative group of the field, i.e. is a primitive
  ++ element.
  ++ Implementation Note that see ch.IX.1.3, th.2 in D. Lipson.
discreteLog: $ -> NonNegativeInteger
  ++ discreteLog(a) computes the discrete logarithm of \spad{a}
  ++ with respect to \spad{primitiveElement()} of the field.
order: $ -> PositiveInteger
  ++ order(b) computes the order of an element b in the multiplicative
  ++ group of the field.
  ++ Error: if b equals 0.
representationType: () -> Union("prime","polynomial","normal","cyclic")
  ++ representationType() returns the type of the representation, one of:
  ++ \spad{prime}, \spad{polynomial}, \spad{normal}, or \spad{cyclic}.

=====
FloatingPointSystem examples
=====
```

This category is intended as a model for floating point systems. A floating point system is a model for the real numbers. In fact, it is an approximation in the sense that not all real numbers are exactly representable by floating point numbers.

A floating point system is characterized by the following:

- 1: base of the exponent where the actual implementations are usually binary or decimal)
- 2: precision of the mantissa (arbitrary or fixed)
- 3: rounding error for operations
- 4: when, and what happens if exponent overflow/underflow occurs

Because a Float is an approximation to the real numbers, even though it is defined to be a join of a Field and OrderedRing, some of the attributes do not hold. In particular associative("+") does not hold. Algorithms defined over a field need special considerations when the field is a floating point system.

**Attributes Exported:**

- **approximate** means “is an approximation to the real numbers”.
- **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is `associates?(a,b)` returns true if and only if `unitCanonical(a) = unitCanonical(b)`.
- **canonicalsClosed** is true if `unitCanonical(a)*unitCanonical(b) = unitCanonical(a*b)`.
- **noZeroDivisors** is true if  $x * y \neq 0$  implies both  $x$  and  $y$  are non-zero.
- **commutative(“\*”)** is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has `unitsKnown` means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .

— category FPS FloatingPointSystem —

```

)abbrev category FPS FloatingPointSystem
++ Description:
++ This category is intended as a model for floating point systems.
++ A floating point system is a model for the real numbers. In fact,
++ it is an approximation in the sense that not all real numbers are
++ exactly representable by floating point numbers.
++ A floating point system is characterized by the following:
++
++ 1: base of the exponent where the actual implemenations are
++ usually binary or decimal)\br
++ 2: precision of the mantissa (arbitrary or fixed)\br
++ 3: rounding error for operations
--++ 4: when, and what happens if exponent overflow/underflow occurs
++
++ Because a Float is an approximation to the real numbers, even though
++ it is defined to be a join of a Field and OrderedRing, some of
++ the attributes do not hold. In particular associative("+")
++ does not hold. Algorithms defined over a field need special
++ considerations when the field is a floating point system.

FloatingPointSystem(): Category == RealNumberSystem() with
  approximate
  ++\spad{approximate} means "is an approximation to the real numbers".
  float: (Integer,Integer) -> %
  ++float(a,e) returns \spad{a * base() ** e}.
  float: (Integer,Integer,PositiveInteger) -> %
  ++float(a,e,b) returns \spad{a * b ** e}.

```

```

order: % -> Integer
  ++order x is the order of magnitude of x.
  ++Note that \spad{base ** order x <= |x| < base ** (1 + order x)}.
base: () -> PositiveInteger
  ++base() returns the base of the
  ++\spadfunFrom{exponent}{FloatingPointSystem}.

exponent: % -> Integer
  ++ exponent(x) returns the
  ++ \spadfunFrom{exponent}{FloatingPointSystem} part of x.

mantissa: % -> Integer
  ++ mantissa(x) returns the mantissa part of x.
-- round?: () -> B
--  ++ round?() returns the rounding or chopping.

bits: () -> PositiveInteger
  ++ bits() returns ceiling's precision in bits.
digits: () -> PositiveInteger
  ++ digits() returns ceiling's precision in decimal digits.
precision: () -> PositiveInteger
  ++ precision() returns the precision in digits base.

if % has arbitraryPrecision then
  bits: PositiveInteger -> PositiveInteger
    ++ bits(n) set the \spadfunFrom{precision}{FloatingPointSystem}
    ++ to n bits.

  digits: PositiveInteger -> PositiveInteger
    ++ digits(d) set the \spadfunFrom{precision}{FloatingPointSystem}
    ++ to d digits.

  precision: PositiveInteger -> PositiveInteger
    ++ precision(n) set the precision in the base to n decimal digits.

  increasePrecision: Integer -> PositiveInteger
    ++ increasePrecision(n) increases the current
    ++ \spadfunFrom{precision}{FloatingPointSystem} by n decimal digits.

  decreasePrecision: Integer -> PositiveInteger
    ++ decreasePrecision(n) decreases the current
    ++ \spadfunFrom{precision}{FloatingPointSystem} precision
    ++ by n decimal digits.

if not (% has arbitraryExponent) then
-- overflow: (()->Exit) -> Void
--  ++ overflow() returns the Exponent overflow of float
-- underflow: (()->Exit) -> Void
--  ++ underflow() returns the Exponent underflow of float
-- maxExponent: () -> Integer

```

```

--    ++ maxExponent() returns the max Exponent of float
    if not (% has arbitraryPrecision) then
        min: () -> %
            ++ min() returns the minimum floating point number.
        max: () -> %
            ++ max() returns the maximum floating point number.

See:

⇒ “MonogenicAlgebra” (MONOGEN) [19](#) on page [1665](#)

⇐ “FiniteRankAlgebra” (FINRALG) [17](#) on page [1393](#)

**Exports:**

0	1	basis
characteristic	characteristicPolynomial	charthRoot
coerce	convert	coordinates
discriminant	hash	latex
minimalPolynomial	norm	one?
rank	recip	regularRepresentation
represents	sample	subtractIfCan
trace	traceMatrix	zero?
?*?	?**?	?+?
?-?	-?	?=?
?^?	?~=?	

**Attributes Exported:**

- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .

These are directly exported but not implemented:

```
basis : () -> Vector %
represents : Vector R -> %
```

These are implemented by this category:

```
convert : Vector R -> %
convert : % -> Vector R
coordinates : Vector % -> Matrix R
coordinates : % -> Vector R
discriminant : () -> R
regularRepresentation : % -> Matrix R
traceMatrix : () -> Matrix R
```

— category **FRAMALG** FramedAlgebra —

```

)abbrev category FRAMALG FramedAlgebra
++ Author: Barry Trager
++ Description:

```

```

++ A \spadtype{FramedAlgebra} is a \spadtype{FiniteRankAlgebra} together
++ with a fixed R-module basis.

FramedAlgebra(R:CommutativeRing, UP:UnivariatePolynomialCategory R):
Category == FiniteRankAlgebra(R, UP) with
  basis          : () -> Vector %
  ++ basis() returns the fixed R-module basis.
  coordinates    : % -> Vector R
  ++ coordinates(a) returns the coordinates of \spad{a} with
  ++ respect to the fixed R-module basis.
  coordinates    : Vector % -> Matrix R
  ++ coordinates([v1,...,vm]) returns the coordinates of the
  ++ vi's with to the fixed basis. The coordinates of vi are
  ++ contained in the ith row of the matrix returned by this
  ++ function.
  represents     : Vector R -> %
  ++ represents([a1,..,an]) returns \spad{a1*v1 + ... + an*vn}, where
  ++ v1, ..., vn are the elements of the fixed basis.
  convert        : % -> Vector R
  ++ convert(a) returns the coordinates of \spad{a} with respect to the
  ++ fixed R-module basis.
  convert        : Vector R -> %
  ++ convert([a1,..,an]) returns \spad{a1*v1 + ... + an*vn}, where
  ++ v1, ..., vn are the elements of the fixed basis.
  traceMatrix    : () -> Matrix R
  ++ traceMatrix() is the n-by-n matrix ( \spad{Tr(vi * vj)} ), where
  ++ v1, ..., vn are the elements of the fixed basis.
  discriminant   : () -> R
  ++ discriminant() = determinant(traceMatrix()).
  regularRepresentation : % -> Matrix R
  ++ regularRepresentation(a) returns the matrix of the linear
  ++ map defined by left multiplication by \spad{a} with respect
  ++ to the fixed basis.

PseudoAlgebraicClosureOfFiniteFieldCategory examples

=====

This category exports the function for the domain  
PseudoAlgebraicClosureOfFiniteField which implement dynamic extension  
using the simple notion of tower extensions.

A tower extension  $T$  of the ground field  $K$  is any sequence of field extension  
( $T : K_0, K_1, \dots, K_i, \dots, K_n$ )  
where  $K_0 = K$  and for  $i = 1, 2, \dots, n$ ,  $K_i$  is an extension  
of  $K_{i-1}$  of degree  $> 1$  and defined by an irreducible polynomial  
 $p(Z)$  in  $K_{i-1}$ .

Two towers

( $T_1 : K_{01}, K_{11}, \dots, K_{i1}, \dots, K_{n1}$ )

and

( $T_2 : K_{02}, K_{12}, \dots, K_{i2}, \dots, K_{n2}$ )

are said to be related if

$T_1 \leq T_2$  (or  $T_1 \geq T_2$ ),

that is if

$K_{i1} = K_{i2}$  for  $i = 1, 2, \dots, n_1$

(or  $i = 1, 2, \dots, n_2$ ). Any algebraic operations defined for several elements  
are only defined if all of the concerned elements are coming from  
a set of related tower extensions.

-?	?/?	?=?
?^?	?~=?	

**Attributes Exported:**

- **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is `associates?(a,b)` returns true if and only if `unitCanonical(a) = unitCanonical(b)`.
- **canonicalsClosed** is true if `unitCanonical(a)*unitCanonical(b) = unitCanonical(a*b)`.
- **noZeroDivisors** is true if  $x * y \neq 0$  implies both x and y are non-zero.
- **commutative(“\*”)** is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has `unitsKnown` means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all x.
- **rightUnitary** is true if  $x * 1 = x$  for all x.

UnivariateLaurentSeriesConstructorCategory examples
=====

```

This is a category of univariate Laurent series constructed from univariate Taylor series. A Laurent series is represented by a pair  $[n, f(x)]$ , where  $n$  is an arbitrary integer and  $f(x)$  is a Taylor series. This pair represents the Laurent series  $x^{*n} * f(x)$ .

**Attributes Exported:**

- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has `unitsKnown` means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .
- if `#1` has `Field` then `canonicalClosed` where **canonicalClosed** is true if `unitCanonical(a)*unitCanonical(b) = unitCanonical(a*b)`.
- if `#1` has `Field` then `canonicalUnitNormal` where **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is `associates?(a,b)` returns true if and only if `unitCanonical(a) = unitCanonical(b)`.
- if `#1` has `CommutativeRing` then `commutative(“*”)` where **commutative(“\*”)** is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- if `#1` has `IntegralDomain` then `noZeroDivisors` where **noZeroDivisors** is true if  $x*y \neq 0$  implies both  $x$  and  $y$  are non-zero.
- if `#1` has `Field` then `nil`

— category ULSCCAT UnivariateLaurentSeriesConstructorCategory

```

)abbrev category ULSCCAT UnivariateLaurentSeriesConstructorCategory
++ Author: Clifton J. Williamson
++ Date Created: 6 February 1990
++ Date Last Updated: 10 May 1990
++ Description:
++ This is a category of univariate Laurent series constructed from
++ univariate Taylor series. A Laurent series is represented by a pair
++ \spad{[n,f(x)]}, where n is an arbitrary integer and \spad{f(x)}
++ is a Taylor series. This pair represents the Laurent series
++ \spad{x**n * f(x)}.

UnivariateLaurentSeriesConstructorCategory(Coef,UTS):_
Category == Definition where
  Coef: Ring
  UTS : UnivariateTaylorSeriesCategory Coef
  I ==> Integer

Definition ==> Join(UnivariateLaurentSeriesCategory(Coef),_
  RetractableTo UTS) with
  laurent: (I,UTS) -> %
    ++ \spad{laurent(n,f(x))} returns \spad{x**n * f(x)}.
  degree: % -> I
    ++ \spad{degree(f(x))} returns the degree of the lowest order term of
    ++ \spad{f(x)}, which may have zero as a coefficient.
  taylorRep: % -> UTS
    ++ \spad{taylorRep(f(x))} returns \spad{g(x)}, where
    ++ \spad{f = x**n * g(x)} is represented by \spad{[n,g(x)]}.
  removeZeroes: % -> %
    ++ \spad{removeZeroes(f(x))} removes leading zeroes from the
    ++ representation of the Laurent series \spad{f(x)}.
    ++ A Laurent series is represented by (1) an exponent and
    ++ (2) a Taylor series which may have leading zero coefficients.
    ++ When the Taylor series has a leading zero coefficient, the
    ++ 'leading zero' is removed from the Laurent series as follows:
    ++ the series is rewritten by increasing the exponent by 1 and
    ++ dividing the Taylor series by its variable.
    ++ Note that \spad{removeZeroes(f)} removes all leading zeroes from f

```

```

removeZeroes: (I,%) -> %
  ++ \spad{removeZeroes(n,f(x))} removes up to n leading zeroes from
  ++ the Laurent series \spad{f(x)}.
  ++ A Laurent series is represented by (1) an exponent and
  ++ (2) a Taylor series which may have leading zero coefficients.
  ++ When the Taylor series has a leading zero coefficient, the
  ++ 'leading zero' is removed from the Laurent series as follows:
  ++ the series is rewritten by increasing the exponent by 1 and
  ++ dividing the Taylor series by its variable.
coerce: UTS -> %
  ++ \spad{coerce(f(x))} converts the Taylor series \spad{f(x)} to a
  ++ Laurent series.
taylor: % -> UTS
  ++ taylor(f(x)) converts the Laurent series f(x) to a Taylor series,
  ++ if possible. Error: if this is not possible.
taylorIfCan: % -> Union(UTS,"failed")
  ++ \spad{taylorIfCan(f(x))} converts the Laurent series \spad{f(x)}
  ++ to a Taylor series, if possible. If this is not possible,
  ++ "failed" is returned.
if Coef has Field then QuotientFieldCategory(UTS)
  --++ the quotient field of univariate Taylor series over a field is
  --++ the field of Laurent series

=====
UnivariatePuisseuxSeriesConstructorCategory examples
=====

```

This is a category of univariate Puiseux series constructed from univariate Laurent series. A Puiseux series is represented by a pair  $[r, f(x)]$ , where  $r$  is a positive rational number and  $f(x)$  is a Laurent series. This pair represents the Puiseux series  $f(x^r)$ .

unitNormal	variable	variables	zero?
?.?	?*?	?**?	?+?
?-?	-?	?=?	?^?
?~=?	?/?	?quo?	?rem?

**Attributes Exported:**

- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation **recip** can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .
- if #1 has Field then canonicalsClosed where
- **canonicalsClosed** is true if  $\text{unitCanonical}(a) * \text{unitCanonical}(b) = \text{unitCanonical}(a * b)$ .

- if #1 has Field then canonicalUnitNormal where **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is `associates?(a,b)` returns true if and only if `unitCanonical(a) = unitCanonical(b)`.
- if #1 has IntegralDomain then noZeroDivisors where **noZeroDivisors** is true if  $x*y \neq 0$  implies both  $x$  and  $y$  are non-zero.
- if #1 has CommutativeRing then commutative(“\*”) where **commutative(“\*”)** is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.

These are directly exported but not implemented:

```
coerce : ULS -> %
degree : % -> Fraction Integer
laurent : % -> ULS
laurentIfCan : % -> Union(ULS,"failed")
laurentRep : % -> ULS
puiseux : (Fraction Integer,ULS) -> %
rationalPower : % -> Fraction Integer
```

These are implemented by this category:

```
retract : % -> ULS
retractIfCan : % -> Union(ULS,"failed")
zero? : % -> Boolean
```

These exports come from (p1524) `UnivariatePuisseuxSeriesCategory(Coef:Ring)`:

— category UPXSCCA UnivariatePuisseuxSeriesConstructorCategory

```

)abbrev category UPXSCCA UnivariatePuisseuxSeriesConstructorCategory
++ Author: Clifton J. Williamson
++ Date Created: 6 February 1990
++ Date Last Updated: 22 March 1990
++ Description:
++ This is a category of univariate Puiseux series constructed
++ from univariate Laurent series. A Puiseux series is represented
++ by a pair \spad{[r,f(x)]}, where r is a positive rational number and
++ \spad{f(x)} is a Laurent series. This pair represents the Puiseux
++ series \spad{f(x^r)}.

UnivariatePuisseuxSeriesConstructorCategory(Coef,ULS):_
Category == Definition where
  Coef : Ring
  ULS : UnivariateLaurentSeriesCategory Coef
  I ==> Integer
  RN ==> Fraction Integer

Definition ==> Join(UnivariatePuisseuxSeriesCategory(Coef),_
  RetractableTo ULS) with
  puiseux: (RN,ULS) -> %
    ++ \spad{puiseux(r,f(x))} returns \spad{f(x^r)}.
  rationalPower: % -> RN
    ++ \spad{rationalPower(f(x))} returns r where the Puiseux series
    ++ \spad{f(x) = g(x^r)}.
  laurentRep : % -> ULS
    ++ \spad{laurentRep(f(x))} returns \spad{g(x)} where the Puiseux series
    ++ \spad{f(x) = g(x^r)} is represented by \spad{[r,g(x)]}.
  degree: % -> RN
    ++ \spad{degree(f(x))} returns the degree of the leading term of the
    ++ Puiseux series \spad{f(x)}, which may have zero as a coefficient.
  coerce: ULS -> %
    ++ \spad{coerce(f(x))} converts the Laurent series \spad{f(x)} to a
    ++ Puiseux series.
  laurent: % -> ULS
    ++ \spad{laurent(f(x))} converts the Puiseux series \spad{f(x)} to a
    ++ Laurent series if possible. Error: if this is not possible.
  laurentIfCan: % -> Union(ULS,"failed")
    ++ \spad{laurentIfCan(f(x))} converts the Puiseux series \spad{f(x)}
    ++ to a Laurent series if possible.
    ++ If this is not possible, "failed" is returned.

=====
FiniteAlgebraicExtensionField examples
=====

```

FiniteAlgebraicExtensionField F is the category of fields  
which are finite algebraic extensions of the field F.

If F is finite then any finite algebraic extension of F is finite, too.  
Let K be a finite algebraic extension of the finite field F. The  
exponentiation of elements of K defines a Z-module structure on the  
multiplicative group of K.

The additive group of K becomes a module over the ring of polynomials  
over F via the operation

```

linearAssociatedExp(a:K,f: SparseUnivariatePolynomial F)

```

which is linear over F, i.e. for elements a from K, c,d from F and  
f,g univariate polynomials over F we have linearAssociatedExp}(a,cf+dg)  
equals c times linearAssociatedExp}(a,f) plus d times  
linearAssociatedExp}(a,g).

Therefore linearAssociatedExp is defined completely by its action on  
monomials from  $F[X]$ : linearAssociatedExp(a,monomial(1,k)\\$SUP(F)) is  
defined to be Frobenius(a,k) which is  $a^{q^k}$  where  $q=\text{size}()\$F$ .

The operations order and discreteLog associated with the multiplicative  
exponentiation have additive analogues associated to the operation  
linearAssociatedExp. These are the functions linearAssociatedOrder  
and linearAssociatedLog, respectively.

**Attributes Exported:**

- **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is `associates?(a,b)` returns true if and only if `unitCanonical(a) = unitCanonical(b)`.
- **canonicalsClosed** is true if `unitCanonical(a)*unitCanonical(b) = unitCanonical(a*b)`.

- **noZeroDivisors** is true if  $x * y \neq 0$  implies both  $x$  and  $y$  are non-zero.
- **commutative**("\*") is true if it has an operation " \*" :  $(D, D) \rightarrow D$  which is commutative.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has **unitsKnown** means that the operation **recip** can only return "failed" if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .

These are directly exported but not implemented:

```

++ Description:
++ FiniteAlgebraicExtensionField F is the category of fields
++ which are finite algebraic extensions of the field F.
++ If F is finite then any finite algebraic extension of F
++ is finite, too. Let K be a finite algebraic extension of the
++ finite field F. The exponentiation of elements of K
++ defines a Z-module structure on the multiplicative group of K.
++ The additive group of K becomes a module over the ring of
++ polynomials over F via the operation
++ \spadfun{linearAssociatedExp}(a:K,f: SparseUnivariatePolynomial F)
++ which is linear over F, that is, for elements a from K,
++ c,d from F and f,g univariate polynomials over F
++ we have \spadfun{linearAssociatedExp}(a,cf+dg) equals c times
++ \spadfun{linearAssociatedExp}(a,f) plus d times
++ \spadfun{linearAssociatedExp}(a,g).
++ Therefore \spadfun{linearAssociatedExp} is defined completely by
++ its action on monomials from F[X]:
++ \spadfun{linearAssociatedExp}(a,monomial(1,k)\$SUP(F)) is defined to be

```

```

++ \spadfun{Frobenius}(a,k) which is  $a^{q^k}$  where  $q=\text{size}()\$F$ .
++ The operations order and discreteLog associated with the multiplicative
++ exponentiation have additive analogues associated to the operation
++ \spadfun{linearAssociatedExp}. These are the functions
++ \spadfun{linearAssociatedOrder} and \spadfun{linearAssociatedLog},
++ respectively.

```

```

FiniteAlgebraicExtensionField(F : Field) : Category == _
  Join(ExtensionField F, RetractableTo F) with
  -- should be unified with algebras
  -- Join(ExtensionField F, FramedAlgebra F, RetractableTo F) with

  basis : () -> Vector $
    ++ basis() returns a fixed basis of \$ as \spad{F}-vectorspace.

  basis : PositiveInteger -> Vector $
    ++ basis(n) returns a fixed basis of a subfield of \$ as
    ++ \spad{F}-vectorspace.

  coordinates : $ -> Vector F
    ++ coordinates(a) returns the coordinates of \spad{a} with respect
    ++ to the fixed \spad{F}-vectorspace basis.

  coordinates : Vector $ -> Matrix F
    ++ coordinates([v1,...,vm]) returns the coordinates of the
    ++ vi's with to the fixed basis. The coordinates of vi are
    ++ contained in the ith row of the matrix returned by this
    ++ function.

  represents: Vector F -> $
    ++ represents([a1,...,an]) returns \spad{a1*v1 + ... + an*vn}, where
    ++ v1,...,vn are the elements of the fixed basis.

  minimalPolynomial: $ -> SparseUnivariatePolynomial F
    ++ minimalPolynomial(a) returns the minimal polynomial of an
    ++ element \spad{a} over the ground field F.

  definingPolynomial: () -> SparseUnivariatePolynomial F
    ++ definingPolynomial() returns the polynomial used to define
    ++ the field extension.

  extensionDegree : () -> PositiveInteger
    ++ extensionDegree() returns the degree of field extension.

  degree : $ -> PositiveInteger
    ++ degree(a) returns the degree of the minimal polynomial of an
    ++ element \spad{a} over the ground field F.

  norm: $ -> F
    ++ norm(a) computes the norm of \spad{a} with respect to the

```

```

++ field considered as an algebra with 1 over the ground field F.

trace: $ -> F
++ trace(a) computes the trace of \spad{a} with respect to
++ the field considered as an algebra with 1 over the ground field F.

if F has Finite then

FiniteFieldCategory

minimalPolynomial: ($,PositiveInteger) -> SparseUnivariatePolynomial $
++ minimalPolynomial(x,n) computes the minimal polynomial of x over
++ the field of extension degree n over the ground field F.

norm: ($,PositiveInteger) -> $
++ norm(a,d) computes the norm of \spad{a} with respect to the field
++ of extension degree d over the ground field of size.
++ Error: if d does not divide the extension degree of \spad{a}.
++ Note that norm(a,d) = reduce(*,[a**(q**(d*i)) for i in 0..n/d])

trace: ($,PositiveInteger) -> $
++ trace(a,d) computes the trace of \spad{a} with respect to the
++ field of extension degree d over the ground field of size q.
++ Error: if d does not divide the extension degree of \spad{a}.
++ Note that
++ \spad{trace(a,d)=reduce(+,[a**(q**(d*i)) for i in 0..n/d])}.

createNormalElement: () -> $
++ createNormalElement() computes a normal element over the ground
++ field F, that is,
++ \spad{a**(q**i), 0 <= i < extensionDegree()} is an F-basis,
++ where \spad{q = size()\$F}.
++ Reference: Such an element exists Lidl/Niederreiter: Theorem 2.35.

normalElement: () -> $
++ normalElement() returns a element, normal over the ground field F,
++ thus \spad{a**(q**i), 0 <= i < extensionDegree()} is an F-basis,
++ where \spad{q = size()\$F}.
++ At the first call, the element is computed by
++ \spadfunFrom{createNormalElement}{FiniteAlgebraicExtensionField}
++ then cached in a global variable.
++ On subsequent calls, the element is retrieved by referencing the
++ global variable.

normal?: $ -> Boolean
++ normal?(a) tests whether the element \spad{a} is normal over the
++ ground field F, that is,
++ \spad{a**(q**i), 0 <= i <= extensionDegree()-1} is an F-basis,
++ where \spad{q = size()\$F}.
++ Implementation according to Lidl/Niederreiter: Theorem 2.39.

```

```

generator: () -> $
  ++ generator() returns a root of the defining polynomial.
  ++ This element generates the field as an algebra over the ground
  ++ field.

linearAssociatedExp: ($, SparseUnivariatePolynomial F) -> $
  ++ linearAssociatedExp(a,f) is linear over F, that is,
  ++ for elements a from \$, c,d form F and
  ++ f,g univariate polynomials over F we have
  ++ \spadfun{linearAssociatedExp}(a,cf+dg) equals c times
  ++ \spadfun{linearAssociatedExp}(a,f) plus d times
  ++ \spadfun{linearAssociatedExp}(a,g). Therefore
  ++ \spadfun{linearAssociatedExp} is defined completely by its
  ++ action on monomials from F[X]:
  ++ \spadfun{linearAssociatedExp}(a,monomial(1,k)\$SUP(F)) is
  ++ defined to be \spadfun{Frobenius}(a,k) which is a**(q**k),
  ++ where q=size()\$F.

linearAssociatedOrder: $ -> SparseUnivariatePolynomial F
  ++ linearAssociatedOrder(a) retruns the monic polynomial g of
  ++ least degree, such that \spadfun{linearAssociatedExp}(a,g) is 0.

linearAssociatedLog: $ -> SparseUnivariatePolynomial F
  ++ linearAssociatedLog(a) returns a polynomial g, such that
  ++ \spadfun{linearAssociatedExp}(normalElement(),g) equals a.

linearAssociatedLog: ($,$) -> _
  Union(SparseUnivariatePolynomial F,"failed")
  ++ linearAssociatedLog(b,a) returns a polynomial g, such
  ++ that the \spadfun{linearAssociatedExp}(b,g) equals a.
  ++ If there is no such polynomial g, then
  ++ \spadfun{linearAssociatedLog} fails.

### Attributes Exported:

- if \$ has Field then canonicalUnitNormal where **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is `associates?(a,b)` returns true if and only if `unitCanonical(a) = unitCanonical(b)`.
- if \$ has Field then canonicalClosed where **canonicalsClosed** is true if `unitCanonical(a)*unitCanonical(b) = unitCanonical(a*b)`.
- if \$ has Field then noZeroDivisors where **noZeroDivisors** is true if  $x * y \neq 0$  implies both x and y are non-zero.
- **commutative(“\*”)** is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation `recip` can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all x.
- **rightUnitary** is true if  $x * 1 = x$  for all x.

These are directly exported but not implemented:

=====
PseudoAlgebraicClosureOfRationalNumberCategory examples
=====

```

This category exports the function for the domain PseudoAlgebraicClosureOfRationalNumber which implement dynamic extension using the simple notion of tower extensions. A tower extension T of the ground field K is any sequence of field extension

$$(T : K_0, K_1, \dots, K_i, \dots, K_n)$$

where  $K_0 = K$  and for  $i = 1, 2, \dots, n$ ,  $K_i$  is an extension of  $K_{i-1}$  of degree  $> 1$  and defined by an irreducible polynomial  $p(Z)$  in  $K_{i-1}$ .

Two towers

$$(T_1: K_{01}, K_{11}, \dots, K_{i1}, \dots, K_{n1})$$

and

$$(T_2: K_{02}, K_{12}, \dots, K_{i2}, \dots, K_{n2})$$

are said to be related if

$$T_1 \leq T_2 \text{ (or } T_1 \geq T_2),$$

that is if

$$K_{i1} = K_{i2} \text{ for } i=1, 2, \dots, n1$$

(or  $i=1, 2, \dots, n2$ ). Any algebraic operations defined for several elements are only defined if all of the concerned elements are coming from a set of related tower extensions.

unitNormal	vectorise	zero?
?*?	?**?	?+?
?-?	-?	?/?
?=?	?~=?	?^?

### Attributes Exported:

- **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is `associates?(a,b)` returns true if and only if `unitCanonical(a) = unitCanonical(b)`.
- **canonicalsClosed** is true if `unitCanonical(a)*unitCanonical(b) = unitCanonical(a*b)`.
- **noZeroDivisors** is true if  $x * y \neq 0$  implies both  $x$  and  $y$  are non-zero.

- **commutative**("\*") is true if it has an operation " $*$ " :  $(D, D) \rightarrow D$  which is commutative.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation **recip** can only return "failed" if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all  $x$ .
- **rightUnitary** is true if  $x * 1 = x$  for all  $x$ .

**Attributes Exported:**

- if #1 has multiplicativeValuation then multiplicativeValuation where **multiplicativeValuation** implies  $\text{euclideanSize}(a*b) = \text{euclideanSize}(a) * \text{euclideanSize}(b)$ .
- if #1 has additiveValuation then additiveValuation where **additiveValuation** implies  $\text{euclideanSize}(a*b) = \text{euclideanSize}(a) + \text{euclideanSize}(b)$ .
- if #1 has Field then canonicalsClosed where **canonicalsClosed** is true if  $\text{unitCanonical}(a) * \text{unitCanonical}(b) = \text{unitCanonical}(a*b)$ .
- if #1 has Field then canonicalUnitNormal where **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is  $\text{associates?}(a,b)$  returns true if and only if  $\text{unitCanonical}(a) = \text{unitCanonical}(b)$ .
- if #1 has IntegralDomain or #1 has both EuclideanDomain and PolynomialFactorizationExplicit then noZeroDivisors where **noZeroDivisors** is true if  $x * y \neq 0$  implies both x and y are non-zero.
- **commutative**("\*") is true if it has an operation " \* " :  $(D, D) \rightarrow D$  which is commutative.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation recip can only return "failed" if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all x.
- **rightUnitary** is true if  $x * 1 = x$  for all x.
- **complex** means that this domain has  $\sqrt{-1}$
- **nil**

**Attributes Exported:**

- if \$ has Fraction(UPOLYC(UFD)) and Field then noZeroDivisors where **noZeroDivisors** is true if  $x * y \neq 0$  implies both x and y are non-zero.
- if \$ has Fraction(UPOLYC(UFD)) and Field then canonicalUnitNormal where **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is **associates?(a,b)** returns true if and only if **unitCanonical(a) = unitCanonical(b)**.
- if \$ has Fraction(UPOLYC(UFD)) and Field then canonicalsClosed where **canonicalsClosed** is true if **unitCanonical(a)\*unitCanonical(b) = unitCanonical(a\*b)**.
- **commutative(“\*”)**  is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation recip can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all x.
- **rightUnitary** is true if  $x * 1 = x$  for all x.

These are directly exported but not implemented:

— category FFCAT FunctionFieldCategory —

```

)abbrev category FFCAT FunctionFieldCategory
++ Author: Manuel Bronstein
++ Date Created: 1987
++ Date Last Updated: 19 Mai 1993
++ Description:
++ Function field of a curve
++ This category is a model for the function field of a
++ plane algebraic curve.

FunctionFieldCategory(F, UP, UPUP): Category == Definition where

```

```

F : UniqueFactorizationDomain
UP : UnivariatePolynomialCategory F
UPUP: UnivariatePolynomialCategory Fraction UP

Z ==> Integer
Q ==> Fraction F
P ==> Polynomial F
RF ==> Fraction UP
QF ==> Fraction UPUP
SY ==> Symbol
REC ==> Record(num:$, den:UP, derivden:UP, gd:UP)

Definition ==> MonogenicAlgebra(RF, UPUP) with

numberOfComponents      : () -> NonNegativeInteger
++numberOfComponents() returns the number of absolutely irreducible
++ components.
++
++X P0 := UnivariatePolynomial(x, Integer)
++X P1 := UnivariatePolynomial(y, Fraction P0)
++X R := RadicalFunctionField(INT, P0, P1, 1 - x**20, 20)
++X numberOfComponents()$R

genus                    : () -> NonNegativeInteger
++genus() returns the genus of one absolutely irreducible component
++
++X P0 := UnivariatePolynomial(x, Integer)
++X P1 := UnivariatePolynomial(y, Fraction P0)
++X R := RadicalFunctionField(INT, P0, P1, 1 - x**20, 20)
++X genus()$R

absolutelyIrreducible? : () -> Boolean
++absolutelyIrreducible?() tests if the curve absolutely irreducible?
++
++X P0 := UnivariatePolynomial(x, Integer)
++X P1 := UnivariatePolynomial(y, Fraction P0)
++X R2 := RadicalFunctionField(INT, P0, P1, 2 * x**2, 4)
++X absolutelyIrreducible?()$R2

rationalPoint?          : (F, F) -> Boolean
++rationalPoint?(a, b) tests if \spad{(x=a,y=b)} is on the curve.
++
++X P0 := UnivariatePolynomial(x, Integer)
++X P1 := UnivariatePolynomial(y, Fraction P0)
++X R := RadicalFunctionField(INT, P0, P1, 1 - x**20, 20)
++X rationalPoint?(0,0)$R
++X R2 := RadicalFunctionField(INT, P0, P1, 2 * x**2, 4)
++X rationalPoint?(0,0)$R2

branchPointAtInfinity? : () -> Boolean

```

```

++branchPointAtInfinity?() tests if there is a branch point
++ at infinity.
++
++X P0 := UnivariatePolynomial(x, Integer)
++X P1 := UnivariatePolynomial(y, Fraction P0)
++X R := RadicalFunctionField(INT, P0, P1, 1 - x**20, 20)
++X branchPointAtInfinity?()$R
++X R2 := RadicalFunctionField(INT, P0, P1, 2 * x**2, 4)
++X branchPointAtInfinity?()$R

branchPoint?          : F -> Boolean
  ++branchPoint?(a) tests whether \spad{x = a} is a branch point.

branchPoint?          : UP -> Boolean
  ++branchPoint?(p) tests whether \spad{p(x) = 0} is a branch point.

singularAtInfinity?  : () -> Boolean
  ++singularAtInfinity?() tests if there is a singularity at infinity.

singular?             : F -> Boolean
  ++singular?(a) tests whether \spad{x = a} is singular.

singular?             : UP -> Boolean
  ++singular?(p) tests whether \spad{p(x) = 0} is singular.

ramifiedAtInfinity?  : () -> Boolean
  ++ramifiedAtInfinity?() tests if infinity is ramified.

ramified?             : F -> Boolean
  ++ramified?(a) tests whether \spad{x = a} is ramified.

ramified?             : UP -> Boolean
  ++ramified?(p) tests whether \spad{p(x) = 0} is ramified.

integralBasis         : () -> Vector $
  ++integralBasis() returns the integral basis for the curve.
  ++
  ++X P0 := UnivariatePolynomial(x, Integer)
  ++X P1 := UnivariatePolynomial(y, Fraction P0)
  ++X R := RadicalFunctionField(INT, P0, P1, 1 - x**20, 20)
  ++X integralBasis()$R

integralBasisAtInfinity: () -> Vector $
  ++integralBasisAtInfinity() returns the local integral basis
  ++ at infinity
  ++
  ++X P0 := UnivariatePolynomial(x, Integer)
  ++X P1 := UnivariatePolynomial(y, Fraction P0)
  ++X R := RadicalFunctionField(INT, P0, P1, 1 - x**20, 20)
  ++X integralBasisAtInfinity()$R

```

```

integralAtInfinity?    : $ -> Boolean
  ++integralAtInfinity?() tests if f is locally integral at infinity.

integral?              : $ -> Boolean
  ++integral?() tests if f is integral over \spad{k[x]}.

complementaryBasis     : Vector $ -> Vector $
  ++complementaryBasis(b1,...,bn) returns the complementary basis
  ++ \spad{(b1',...,bn')} of \spad{(b1,...,bn)}.

normalizeAtInfinity     : Vector $ -> Vector $
  ++normalizeAtInfinity(v) makes v normal at infinity.

reduceBasisAtInfinity : Vector $ -> Vector $
  ++reduceBasisAtInfinity(b1,...,bn) returns \spad{(x**i * bj)}
  ++ for all i,j such that \spad{x**i*bj} is locally integral
  ++ at infinity.

integralMatrix         : () -> Matrix RF
  ++integralMatrix() returns M such that
  ++ \spad{(w1,...,wn) = M (1, y, ..., y**(n-1))},
  ++ where \spad{(w1,...,wn)} is the integral basis of
  ++ \spadfunFrom{integralBasis}{FunctionFieldCategory}.
  ++
  ++X P0 := UnivariatePolynomial(x, Integer)
  ++X P1 := UnivariatePolynomial(y, Fraction P0)
  ++X R := RadicalFunctionField(INT, P0, P1, 1 - x**20, 20)
  ++X integralMatrix()$R

inverseIntegralMatrix : () -> Matrix RF
  ++inverseIntegralMatrix() returns M such that
  ++ \spad{M (w1,...,wn) = (1, y, ..., y**(n-1))}
  ++ where \spad{(w1,...,wn)} is the integral basis of
  ++ \spadfunFrom{integralBasis}{FunctionFieldCategory}.
  ++
  ++X P0 := UnivariatePolynomial(x, Integer)
  ++X P1 := UnivariatePolynomial(y, Fraction P0)
  ++X R := RadicalFunctionField(INT, P0, P1, 1 - x**20, 20)
  ++X inverseIntegralMatrix()$R

integralMatrixAtInfinity : () -> Matrix RF
  ++integralMatrixAtInfinity() returns M such that
  ++ \spad{(v1,...,vn) = M (1, y, ..., y**(n-1))}
  ++ where \spad{(v1,...,vn)} is the local integral basis at infinity
  ++ returned by \spad{infIntBasis()}.
  ++
  ++X P0 := UnivariatePolynomial(x, Integer)
  ++X P1 := UnivariatePolynomial(y, Fraction P0)
  ++X R := RadicalFunctionField(INT, P0, P1, 1 - x**20, 20)

```

```

++X integralMatrixAtInfinity()$R

inverseIntegralMatrixAtInfinity: () -> Matrix RF
++inverseIntegralMatrixAtInfinity() returns M such
++ that \spad{M (v1,...,vn) = (1, y, ..., y**(n-1))}
++ where \spad{(v1,...,vn)} is the local integral basis at infinity
++ returned by \spad{infIntBasis()}.
++
++X P0 := UnivariatePolynomial(x, Integer)
++X P1 := UnivariatePolynomial(y, Fraction P0)
++X R := RadicalFunctionField(INT, P0, P1, 1 - x**20, 20)
++X inverseIntegralMatrixAtInfinity()$R

yCoordinates          : $ -> Record(num:Vector(UP), den:UP)
++yCoordinates(f) returns \spad{[[A1,...,An], D]} such that
++ \spad{f = (A1 + A2 y + ... + An y**(n-1)) / D}.

represents            : (Vector UP, UP) -> $
++represents([A0,...,A(n-1)],D) returns
++ \spad{(A0 + A1 y + ... + A(n-1)*y**(n-1))/D}.

integralCoordinates   : $ -> Record(num:Vector(UP), den:UP)
++integralCoordinates(f) returns \spad{[[A1,...,An], D]} such that
++ \spad{f = (A1 w1 + ... + An wn) / D} where \spad{(w1,...,wn)} is the
++ integral basis returned by \spad{integralBasis()}.

integralRepresents    : (Vector UP, UP) -> $
++integralRepresents([A1,...,An], D) returns
++ \spad{(A1 w1+...+An wn)/D}
++ where \spad{(w1,...,wn)} is the integral
++ basis of \spad{integralBasis()}.

integralDerivationMatrix:(UP -> UP) -> Record(num:Matrix(UP),den:UP)
++integralDerivationMatrix(d) extends the derivation d from UP to $
++ and returns (M, Q) such that the ith row of M divided by Q form
++ the coordinates of \spad{d(wi)} with respect to \spad{(w1,...,wn)}
++ where \spad{(w1,...,wn)} is the integral basis returned
++ by integralBasis().

integral?             : ($, F) -> Boolean
++integral?(f, a) tests whether f is locally integral at \spad{x = a}.

integral?             : ($, UP) -> Boolean
++integral?(f, p) tests whether f is locally integral at
++ \spad{p(x) = 0}

differentiate         : ($, UP -> UP) -> $
++differentiate(x, d) extends the derivation d from UP to $ and
++ applies it to x.

```

```

represents          : (Vector UP, UP) -> $
++represents([A0,...,A(n-1)],D) returns
++ \spad{(A0 + A1 y +...+ A(n-1)*y**(n-1))/D}.

primitivePart      : $ -> $
++primitivePart(f) removes the content of the denominator and
++ the common content of the numerator of f.

elt                : ($, F, F) -> F
++elt(f,a,b) or f(a, b) returns the value of f
++ at the point \spad{(x = a, y = b)}
++ if it is not singular.

elliptic           : () -> Union(UP, "failed")
++elliptic() returns \spad{p(x)} if the curve is the elliptic
++ defined by \spad{y**2 = p(x)}, "failed" otherwise.

hyperelliptic     : () -> Union(UP, "failed")
++hyperelliptic() returns \spad{p(x)} if the curve is the
++ hyperelliptic
++ defined by \spad{y**2 = p(x)}, "failed" otherwise.

algSplitSimple     : ($, UP -> UP) -> REC
++algSplitSimple(f, D) returns \spad{[h,d,d',g]} such that
++ \spad{f=h/d},
++ \spad{h} is integral at all the normal places w.r.t. \spad{D},
++ \spad{d' = Dd}, \spad{g = gcd(d, discriminant())} and \spad{D}
++ is the derivation to use. \spad{f} must have at most simple finite
++ poles.

if F has Field then

    nonSingularModel: SY -> List Polynomial F
    ++nonSingularModel(u) returns the equations in u1,...,un of
    ++ an affine non-singular model for the curve.

if F has Finite then

    rationalPoints: () -> List List F
    ++rationalPoints() returns the list of all the affine
    ++rational points.

=====
PseudoAlgebraicClosureOfAlgExtOfRationalNumberCategory examples
=====

```

This category exports the function for the domain  
PseudoAlgebraicClosureOfAlgExtOfRationalNumber which implement dynamic  
extension using the simple notion of tower extensions. A tower extension  
T of the ground field K is any sequence of field extension  
 $(T : K_0, K_1, \dots, K_i, \dots, K_n)$   
where  $K_0 = K$  and for  $i = 1, 2, \dots, n$ ,  
 $K_i$  is an extension of  $K_{i-1}$  of degree  $> 1$   
and defined by an irreducible polynomial  $p(Z)$  in  $K_{i-1}$ .

Two towers  
 $(T_1: K_{01}, K_{11}, \dots, K_{i1}, \dots, K_{n1})$   
and  
 $(T_2: K_{02}, K_{12}, \dots, K_{i2}, \dots, K_{n2})$   
are said to be related if  
 $T_1 \leq T_2$  (or  $T_1 \geq T_2$ ),

that is if

$K_{i1} = K_{i2}$  for  $i=1,2,\dots,n1$  (or  $i=1,2,\dots,n2$ ).

Any algebraic operations defined for several elements are only defined if all of the concerned elements are coming from a set of related tower extensions.

### Attributes Exported:

- **commutative**(“\*”) is true if it has an operation “\*” :  $(D, D) \rightarrow D$  which is commutative.
- **unitsKnown** is true if a monoid (a multiplicative semigroup with a 1) has unitsKnown means that the operation **recip** can only return “failed” if its argument is not a unit.
- **leftUnitary** is true if  $1 * x = x$  for all x.
- **rightUnitary** is true if  $x * 1 = x$  for all x.

- **noZeroDivisors** is true if  $x * y \neq 0$  implies both  $x$  and  $y$  are non-zero.
- **canonicalUnitNormal** is true if we can choose a canonical representative for each class of associate elements, that is **associates?(a,b)** returns true if and only if **unitCanonical(a) = unitCanonical(b)**.
- **canonicalsClosed** is true if **unitCanonical(a)\*unitCanonical(b) = unitCanonical(a\*b)**.

# Chapter 21

## The bootstrap code

### 21.1 ABELGRP.lsp BOOTSTRAP

**ABELGRP** depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **ABELGRP** category which we can write into the **MID** directory. We compile the lisp code and copy the **ABELGRP.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

— ABELGRP.lsp BOOTSTRAP —

```
(|/VERSIONCHECK| 2)

(SETQ |AbelianGroup;AL| (QUOTE NIL))

(DEFUN |AbelianGroup| NIL
  (LET (#:G82664)
    (COND
      (|AbelianGroup;AL|)
      (T (SETQ |AbelianGroup;AL| (|AbelianGroup;|))))))

(DEFUN |AbelianGroup;| NIL
  (PROG (#1=:G82662)
    (RETURN
      (PROG1
        (LETT #1#
          (|Join|
            (|CancellationAbelianMonoid|)

## 21.18 EUCDOM.lsp BOOTSTRAP

**EUCDOM** depends on **INT** which depends on **EUCDOM**. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **EUCDOM** category which we can write into the **MID** directory. We compile the lisp code and copy the **EUCDOM.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

### The Lisp Implementation

#### **EUCDOM;VersionCheck**

This implements the bootstrap code for **EuclideanDomain**. The call to **VERSIONCHECK** is a legacy check to ensure that we did not load algebra code from a previous system version (which would not run due to major surgical changes in the system) without recompiling.

— **EUCDOM;VersionCheck** —

```
(|/VERSIONCHECK| 2)
```

---

### The Domain Cache Variable

We create a variable which is formed by concatenating the string “;AL” to the domain name forming, in this case, “**EuclideanDomain;AL**”. The variable has the initial value at load time of a list of one element, **NIL**. This list is a data structure that will be modified to hold an executable function. This function is created the first time the domain is used which it replaces the **NIL**.

— **EuclideanDomain;AL** —

```
(SETQ |EuclideanDomain;AL| (QUOTE NIL))
```

### The Domain Function

When you call a domain the code is pretty simple at the top level. This code will check to see if this domain has ever been used. It does this by checking the value of the cached domain variable (which is the domain name **EuclideanDomain** concatenated with the string “;AL” to form the cache variable name which is **EuclideanDomain;AL**).

If this value is **NIL** we have never executed this function before. If it is not **NIL** we have executed this function before and we need only return the cached function which was stored in the cache variable.

If this is the first time this function is called, the cache variable is **NIL** and we execute the other branch of the conditional. This calls a function which

1. creates a procedure
2. returns the procedure as a value.

This procedure replaces the cached variable **EuclideanDomain;AL** value so it will be non-**NIL** the second time this domain is used. Thus the work of building the domain only happens once.

If this function has never been called before we call the

## 21.20 ENTIRER.lsp BOOTSTRAP

**ENTIRER** depends on itself. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **ENTIRER** category which we can write into the **MID** directory. We compile the lisp code and copy the **ENTIRER.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

## 21.23 FPS.lsp BOOTSTRAP

**FPS** depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **FPS** category which we can write into the **MID** directory. We compile the lisp code and copy the **FPS.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

## — FPS.lsp BOOTSTRAP —

## 21.28 HOAGG-.lsp BOOTSTRAP

**HOAGG-** depends on **HOAGG**. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **HOAGG-** category which we can write into the **MID** directory. We compile the lisp code and copy the **HOAGG-.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

## 21.30 INS-.lsp BOOTSTRAP

**INS-** depends on **INS**. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **INS-** category which we can write into the **MID** directory. We compile the lisp code and copy the **INS-.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

— **INS-.lsp BOOTSTRAP** —

## 21.37 MONOID.lsp BOOTSTRAP

**MONOID** depends on itself. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **MONOID** category which we can write into the **MID** directory. We compile the lisp code and copy the **MONOID.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

```

## 21.41 **ORDRING.lsp BOOTSTRAP**

**ORDRING** depends on **INT**. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **ORDRING** category which we can write into the **MID** directory. We compile the lisp code and copy the **ORDRING.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Technically I can't justify this bootstrap stanza based on the lattice since **INT** is already bootstrapped. However using **INT** naked generates a "value stack overflow" error suggesting an infinite recursive loop. This code is here to experiment with breaking that loop.

Note that this code is not included in the generated catdef.spad file.

## 21.45 PSETCAT.lsp BOOTSTRAP

**PSETCAT** depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **PSETCAT** category which we can write into the **MID** directory. We compile the lisp code and copy the **PSETCAT.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

## 21.47 QFCAT.lsp BOOTSTRAP

**QFCAT** depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **QFCAT** category which we can write into the **MID** directory. We compile the lisp code and copy the **QFCAT.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

## 21.48 QFCAT-.lsp BOOTSTRAP

**QFCAT-** depends on **QFCAT**. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **QFCAT-** category which we can write into the **MID** directory. We compile the lisp code and copy the **QFCAT-.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

```

## 21.59 SETCAT-.lsp BOOTSTRAP

**SETCAT-** is the implementation of the operations exported by **SETCAT**. It comes into existence whenever **SETCAT** gets compiled by Axiom. However this will not happen at the lisp level so we also cache this information here. See the explanation under the **SETCAT.lsp** section for more details.

Note that this code is not included in the generated catdef.spad file.

## 21.62 TSETCAT.lsp BOOTSTRAP

**TSETCAT** depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **TSETCAT** category which we can write into the **MID** directory. We compile the lisp code and copy the **TSETCAT.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

## 21.63 TSETCAT-.lsp BOOTSTRAP

**TSETCAT** depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **TSETCAT** category which we can write into the **MID** directory. We compile the lisp code and copy the **TSETCAT.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

## — TSETCAT-.lsp BOOTSTRAP —

## 21.64 UFD.lsp BOOTSTRAP

**UFD** needs **GCDDOM** which needs **COMRING** which needs **RING** which needs **RNG** which needs **ABELGRP** which needs **CABMON** which needs **ABELMON** which needs **ABELSG** which needs **SETCAT** which needs **SINT** which needs **UFD**. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **UFD** category which we can write into the **MID** directory. We compile the lisp code and copy the **UFD.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

## 21.67 UPOLYC.lsp BOOTSTRAP

**UPOLYC** depends on itself. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **UPOLYC** category which we can write into the **MID** directory. We compile the lisp code and copy the **UPOLYC.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

## 21.69 URAGG.lsp BOOTSTRAP

**URAGG** depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **URAGG** category which we can write into the **MID** directory. We compile the lisp code and copy the **URAGG.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.
