=====
 IndexedFlexibleArray examples
 =====

A FlexibleArray is the notion of an array intended to allow for growth at the end only. Hence the following efficient operations
 append(x,a) meaning append item x at the end of the array a
 delete(a,n)} meaning delete the last item from the array a

Flexible arrays support the other operations inherited from ExtensibleLinearAggregate. However, these are not efficient.

Flexible arrays combine the O(1) access time property of arrays with growing and shrinking at the end in O(1) (average) time. This is done by using an ordinary array which may have zero or more empty slots at the end. When the array becomes full it is copied into a new larger (50% larger) array. Conversely, when the array becomes less than 1/2 full, it is copied into a smaller array. Flexible arrays provide for an efficient implementation of many data structures in particular heaps, stacks and sets.

=====
IndexedList examples
=====

```

IndexedList is a basic implementation of the functions in ListAggregate, often using functions in the underlying LISP system. The second parameter to the constructor (mn) is the beginning index of the list. That is, if l is a list, then elt(l,mn) is the first value. This constructor is probably best viewed as the implementation of singly-linked lists that are addressable by index rather than as a mere wrapper for LISP lists.

=====
IndexedMatrix examples
=====

```

An IndexedMatrix is a matrix where the minimal row and column indices are parameters of the type. The domains Row and Col are both IndexedVectors.

The index of the 'first' row may be obtained by calling the function minRowIndex. The index of the 'first' column may be obtained by calling the function minColIndex. The index of the first element of a 'Row' is the same as the index of the first column in a matrix and vice versa.

— domain IMATRIX IndexedMatrix —

```

)abbrev domain IMATRIX IndexedMatrix
++ Author: Grabmeier, Gschnitzer, Williamson
++ Date Created: 1987
++ Date Last Updated: July 1990
++ Description:
++ An \spad{IndexedMatrix} is a matrix where the minimal row and column
++ indices are parameters of the type. The domains Row and Col
++ are both IndexedVectors.
++ The index of the 'first' row may be obtained by calling the
++ function \spadfun{minRowIndex}. The index of the 'first' column may
++ be obtained by calling the function \spadfun{minColIndex}. The index of
++ the first element of a 'Row' is the same as the index of the
  
```

```

++ first column in a matrix and vice versa.

domain IARRAY2 IndexedTwoDimensionalArray

An IndexedTwoDimensionalArray is a 2-dimensional array where the minimal row and column indices are parameters of the type. Rows and columns are returned as IndexedOneDimensionalArray's with minimal indices matching those of the IndexedTwoDimensionalArray. The index of the 'first' row may be obtained by calling the function 'minRowIndex'. The index of the 'first' column may be obtained by calling the function 'minColIndex'. The index of the first element of a 'Row' is the same as the index of the first column in an array and vice versa.

  makeSeries: (REF,ST) -> %
    ++ makeSeries(refer,str) creates a power series from the reference
    ++ \spad{refer} and the stream \spad{str}.
  getRef: % -> REF
    ++ getRef(f) returns a reference containing the order to which the
    ++ terms of f have been computed.
  getStream: % -> ST
    ++ getStream(f) returns the stream of terms representing the series f.
  series: ST -> %
    ++ series(st) creates a series from a stream of non-zero terms,
    ++ where a term is an exponent-coefficient pair. The terms in the
    ++ stream should be ordered by increasing order of exponents.
  monomial?: % -> B
    ++ monomial?(f) tests if f is a single monomial.
  multiplyCoefficients: (I -> Coef,%) -> %
    ++ multiplyCoefficients(fn,f) returns the series
    ++ \spad{sum(fn(n) * an * x^n,n = n0..)},
    ++ where f is the series \spad{sum(an * x^n,n = n0..)}.
  iExquo: (%,% ,B) -> Union(%, "failed")
    ++ iExquo(f,g,taylor?) is the quotient of the power series f and g.
    ++ If \spad{taylor?} is \spad{true}, then we must have
    ++ \spad{order(f) >= order(g)}.
  taylorQuoByVar: % -> %
    ++ taylorQuoByVar(a0 + a1 x + a2 x**2 + ...)
    ++ returns \spad{a1 + a2 x + a3 x**2 + ...}
  iCompose: (%,% ) -> %
    ++ iCompose(f,g) returns \spad{f(g(x))}. This is an internal function
    ++ which should only be called for Taylor series \spad{f(x)} and
    ++ \spad{g(x)} such that the constant coefficient of \spad{g(x)} is zero.
  seriesToOutputForm: (ST,REF,Symbol,Coef,RN) -> OutputForm
    ++ seriesToOutputForm(st,refer,var,cen,r) prints the series
    ++ \spad{f((var - cen)^r)}.

```

```

if Coef has Algebra Fraction Integer then
integrate: % -> %
  ++ integrate(f(x)) returns an anti-derivative of the power series
  ++ \spad{f(x)} with constant coefficient 0.
  ++ Warning: function does not check for a term of degree -1.
cPower: (% ,Coef) -> %
  ++ cPower(f,r) computes \spad{f^r}, where f has constant coefficient 1.
  ++ For use when the coefficient ring is commutative.
cRationalPower: (% ,RN) -> %
  ++ cRationalPower(f,r) computes \spad{f^r}.
  ++ For use when the coefficient ring is commutative.
cExp: % -> %
  ++ cExp(f) computes the exponential of the power series f.
  ++ For use when the coefficient ring is commutative.
cLog: % -> %
  ++ cLog(f) computes the logarithm of the power series f.
  ++ For use when the coefficient ring is commutative.
cSin: % -> %
  ++ cSin(f) computes the sine of the power series f.
  ++ For use when the coefficient ring is commutative.

```
coefficients: % -> Stream Coef
++\spad{coefficients(x)} returns a stream of ring elements.
++ When x is a univariate series, this is a stream of Taylor
```

```

++ coefficients. When x is a multivariate series, the
++ \spad{n}th element of the stream is a form of
++ degree n in the power series variables.
series: Stream Coef -> %
++\spad{series(s)} creates a power series from a stream of
++ ring elements.
++ For univariate series types, the stream s should be a stream
++ of Taylor coefficients. For multivariate series types, the
++ stream s should be a stream of forms the \spad{n}th element
++ of which is a
++ form of degree n in the power series variables.
pole?: % -> Boolean
++\spad{pole?(x)} tests if the series x has a pole.
++ Note: this is false when x is a Taylor series.
order: % -> NNI
++\spad{order(x)} returns the order of a power series x,
++ i.e. the degree of the first non-zero term of the series.
order: (% , NNI) -> NNI
++\spad{order(x,n)} returns the minimum of n and the order of x.
"*" : (Coef,%) -> %
++\spad{c*x} returns the product of c and the series x.
"*" : (% , Coef) -> %
++\spad{x*c} returns the product of c and the series x.
"*" : (% , Integer) -> %
++\spad{x*i} returns the product of integer i and the series x.

)abbrev domain INFORM InputForm
++ Author: Manuel Bronstein
++ Date Last Updated: 19 April 1991
++ Description:
++ Domain of parsed forms which can be passed to the interpreter.
++ This is also the interface between algebra code and facilities
++ in the interpreter.

-->boot $noSubsumption := true

InputForm():
  Join(SExpressionCategory(String,Symbol,Integer,DoubleFloat,OutputForm),
    ConvertibleTo SExpression) with
  interpret: % -> Any
    ++ interpret(f) passes f to the interpreter.
  convert : SExpression -> %
    ++ convert(s) makes s into an input form.
  binary : (% , List %) -> %
    ++ \spad{binary(op, [a1,...,an])} returns the input form
    ++ corresponding to \spad{a1 op a2 op ... op an}.
    ++
    ++X a:=[1,2,3]::List(InputForm)
    ++X binary(_+::InputForm,a)

```

```

function : (% , List Symbol, Symbol) -> %
  ++ \spad{function(code, [x1,...,xn], f)} returns the input form
  ++ corresponding to \spad{f(x1,...,xn) == code}.
lambda   : (% , List Symbol) -> %
  ++ \spad{lambda(code, [x1,...,xn])} returns the input form
  ++ corresponding to \spad{(x1,...,xn) +-> code} if \spad{n > 1},
  ++ or to \spad{x1 +-> code} if \spad{n = 1}.
"+"      : (% , %) -> %
  ++ \spad{a + b} returns the input form corresponding to \spad{a + b}.
"*"      : (% , %) -> %
  ++ \spad{a * b} returns the input form corresponding to \spad{a * b}.
"/"      : (% , %) -> %
  ++ \spad{a / b} returns the input form corresponding to \spad{a / b}.
"*)"     : (% , NonNegativeInteger) -> %
  ++ \spad{a ** b} returns the input form corresponding to \spad{a ** b}.
"*)"     : (% , Integer) -> %
  ++ \spad{a ** b} returns the input form corresponding to \spad{a ** b}.
0        : constant -> %
  ++ \spad{0} returns the input form corresponding to 0.
1        : constant -> %
  ++ \spad{1} returns the input form corresponding to 1.
flatten  : % -> %
  ++ flatten(s) returns an input form corresponding to s with
  ++ all the nested operations flattened to triples using new
  ++ local variables.
  ++ If s is a piece of code, this speeds up
  ++ the compilation tremendously later on.
unparse  : % -> String
  ++ unparse(f) returns a string s such that the parser
  ++ would transform s to f.
  ++ Error: if f is not the parsed form of a string.
parse    : String -> %
  ++ parse(s) is the inverse of unparse. It parses a string to InputForm.
declare  : List % -> Symbol
  ++ declare(t) returns a name f such that f has been
  ++ declared to the interpreter to be of type t, but has
  ++ not been assigned a value yet.
  ++ Note: t should be created as \spad{devaluate(T)$Lisp} where T is the
  ++ actual type of f (this hack is required for the case where
  ++ T is a mapping type).
compile  : (Symbol, List %) -> Symbol
  ++ \spad{compile(f, [t1,...,tn])} forces the interpreter to compile
  ++ the function f with signature \spad{(t1,...,tn) -> ?}.
  ++ returns the symbol f if successful.
  ++ Error: if f was not defined beforehand in the interpreter,
  ++ or if the ti's are not valid types, or if the compiler fails.

Integer examples
=====

Axiom provides many operations for manipulating arbitrary precision integers. In this section we will show some of those that come from Integer itself plus some that are implemented in other packages.

\subsection{Basic Functions}

The size of an integer in Axiom is only limited by the amount of computer storage you have available. The usual arithmetic operations are available.

```

2**(5678 - 4856 + 2 * 17)
4804810770435008147181540925125924391239526139871682263473855610088084200076_
308293086342527091412083743074572278211496076276922026433435687527334980249_
539302425425230458177649495442143929053063884787051467457680738771416988598_
15495632935288783334250628775936
Type: PositiveInteger

```

There are a number of ways of working with the sign of an integer. Let's use this x as an example.

```

x := -101
- 101
Type: Integer

```

First of all, there is the absolute value function.

```
abs(x)
101
Type: PositiveInteger
```

The sign operation returns -1 if its argument is negative, 0 if zero and 1 if positive.

```
sign(x)
- 1
Type: Integer
```

You can determine if an integer is negative in several other ways.

```
x < 0
true
Type: Boolean
```

```
x <= -1
true
Type: Boolean
```

```
negative?(x)
true
Type: Boolean
```

Similarly, you can find out if it is positive.

```
x > 0
false
Type: Boolean
```

```
x >= 1
false
Type: Boolean
```

```
positive?(x)
false
Type: Boolean
```

This is the recommended way of determining whether an integer is zero.

```
zero?(x)
false
Type: Boolean
```

Use the zero? operation whenever you are testing any mathematical object for equality with zero. This is usually more efficient than using = (think of matrices: it is easier to tell if a matrix is zero

by just checking term by term than constructing another "zero" matrix and comparing the two matrices term by term) and also avoids the problem that = is usually used for creating equations.

This is the recommended way of determining whether an integer is equal to one.

```
one?(x)
  false
                                Type: Boolean
```

This syntax is used to test equality using =. It says that you want a Boolean (true or false) answer rather than an equation.

```
(x = -101)@Boolean
  true
                                Type: Boolean
```

The operations odd? and even? determine whether an integer is odd or even, respectively. They each return a Boolean object.

```
odd?(x)
  true
                                Type: Boolean
```

```
even?(x)
  false
                                Type: Boolean
```

The operation gcd computes the greatest common divisor of two integers.

```
gcd(56788,43688)
  4
                                Type: PositiveInteger
```

The operation lcm computes their least common multiple.

```
lcm(56788,43688)
  620238536
                                Type: PositiveInteger
```

To determine the maximum of two integers, use max.

```
max(678,567)
  678
                                Type: PositiveInteger
```

To determine the minimum, use min.

```
min(678,567)
```

567

Type: PositiveInteger

The reduce operation is used to extend binary operations to more than two arguments. For example, you can use reduce to find the maximum integer in a list or compute the least common multiple of all integers in the list.

```
reduce(max,[2,45,-89,78,100,-45])
```

100

Type: PositiveInteger

```
reduce(min,[2,45,-89,78,100,-45])
```

- 89

Type: Integer

```
reduce(gcd,[2,45,-89,78,100,-45])
```

1

Type: PositiveInteger

```
reduce(lcm,[2,45,-89,78,100,-45])
```

1041300

Type: PositiveInteger

The infix operator "/" is not used to compute the quotient of integers. Rather, it is used to create rational numbers as described in Fraction.

```
13 / 4
```

13

--

4

Type: Fraction Integer

The infix operation quo computes the integer quotient.

```
13 quo 4
```

3

Type: PositiveInteger

The infix operation rem computes the integer remainder.

```
13 rem 4
```

1

Type: PositiveInteger

One integer is evenly divisible by another if the remainder is zero. The operation exquo can also be used.

```
zero?(167604736446952 rem 2003644)
```

true

Type: Boolean

The operation divide returns a record of the quotient and remainder and thus is more efficient when both are needed.

```
d := divide(13,4)
  [quotient= 3,remainder= 1]
                                Type: Record(quotient: Integer,remainder: Integer)
```

```
d.quotient
  3
                                Type: PositiveInteger
```

See help on Records for details on Records.

```
d.remainer
  1
                                Type: PositiveInteger
```

```
=====
Primes and Factorization
=====
```

Use the operation factor to factor integers. It returns an object of type Factored Integer.

```
factor 102400
  12 2
  2  5
                                Type: Factored Integer
```

The operation prime? returns true or false depending on whether its argument is a prime.

```
prime? 7
  true
                                Type: Boolean
```

```
prime? 8
  false
                                Type: Boolean
```

The operation nextPrime returns the least prime number greater than its argument.

```
nextPrime 100
  101
                                Type: PositiveInteger
```

The operation prevPrime returns the greatest prime number less than

its argument.

```
prevPrime 100
97
Type: PositiveInteger
```

To compute all primes between two integers (inclusively), use the operation `primes`.

```
primes(100,175)
[173,167,163,157,151,149,139,137,131,127,113,109,107,103,101]
Type: List Integer
```

You might sometimes want to see the factorization of an integer when it is considered a Gaussian integer.

```
factor(2 :: Complex Integer)
      2
- %i (1 + %i)
Type: Factored Complex Integer
```

=====

Some Number Theoretic Functions

=====

Axiom provides several number theoretic operations for integers.

The operation `fibonacci` computes the Fibonacci numbers. The algorithm has running time $O(\log^3 n)$ for argument n .

```
[fibonacci(k) for k in 0..]
[0,1,1,2,3,5,8,13,21,34,...]
Type: Stream Integer
```

The operation `legendre` computes the Legendre symbol for its two integer arguments where the second one is prime. If you know the second argument to be prime, use `jacobi` instead where no check is made.

```
[legendre(i,11) for i in 0..10]
[0,1,- 1,1,1,1,- 1,- 1,- 1,1,- 1]
Type: List Integer
```

The operation `jacobi` computes the Jacobi symbol for its two integer arguments. By convention, 0 is returned if the greatest common divisor of the numerator and denominator is not 1.

```
[jacobi(i,15) for i in 0..9]
[0,1,1,0,1,0,0,- 1,1,0]
Type: List Integer
```

The operation `eulerPhi` computes the values of Euler's ϕ -function where $\phi(n)$ equals the number of positive integers less than or equal to n that are relatively prime to the positive integer n .

```
[eulerPhi i for i in 1..]
  [1,1,2,2,4,2,6,4,6,4,...]
      Type: Stream Integer
```

The operation `moebiusMu` computes the Moebius μ function.

```
[moebiusMu i for i in 1..]
  [1,- 1,- 1,0,- 1,1,- 1,0,0,1,...]
      Type: Stream Integer
```

=====
IntegrationResult examples
=====

```

The result of a transcendental integration.

If a function f has an elementary integral g , then g can be written in the form

$$g = h + c_1 \log(u_1) + c_2 \log(u_2) + \dots + c_n \log(u_n)$$

where h , which is in the same field than f , is called the rational part of the integral, and

$$c_1 \log(u_1) + \dots + c_n \log(u_n)$$

is called the logarithmic part of the integral. This domain manipulates integrals represented in that form, by keeping both parts separately. The logs are not explicitly computed.

 — Kernel.help —

```
=====
Kernel examples
=====
```

A kernel is a symbolic function application (such as $\sin(x+y)$) or a symbol (such as x). More precisely, a non-symbol kernel over a set S is an operator applied to a given list of arguments from S . The operator has type `BasicOperator` and the kernel object is usually part of an `Expression` object.

Kernels are created implicitly for you when you create expressions.

```
x :: Expression Integer
x
Type: Expression Integer
```

You can directly create a "symbol" kernel by using the kernel operation.

```
kernel x
x
Type: Kernel Expression Integer
```

This expression has two different kernels.

```
sin(x) + cos(x)
sin(x) + cos(x)
Type: Expression Integer
```

The operator `kernels` returns a list of the kernels in an object of type `Expression`.

Conceptually, an object of type `Expression` can be thought of a quotient of multivariate polynomials, where the "variables" are kernels. The arguments of the kernels are again expressions and so the structure recurses. See `Expression` for examples of using kernels to take apart expression objects.

=====
KeyedAccessFile examples
=====

```

The domain KeyedAccessFile(S) provides files which can be used as associative tables. Data values are stored in these files and can be retrieved according to their keys. The keys must be strings so this type behaves very much like the StringTable(S) domain. The difference is that keyed access files reside in secondary storage while string tables are kept in memory.

Before a keyed access file can be used, it must first be opened. A new file can be created by opening it for output.

```
ey: KeyedAccessFile(Integer) := open("editor.year", "output")
```

Just as for vectors, tables or lists, values are saved in a keyed access file by setting elements.

```
ey."Char" := 1986
```

```
ey."Caviness" := 1985
```

```
ey."Fitch" := 1984
```

Values are retrieved using application, in any of its syntactic forms.

```
ey."Char"
```

```
ey("Char")
```

```
ey "Char"
```

Attempting to retrieve a non-existent element in this way causes an error. If it is not known whether a key exists, you should use the search operation.

```
search("Char", ey)
```

```
search("Smith", ey)
```

When an entry is no longer needed, it can be removed from the file.

```
remove!("Char", ey)
```

The keys operation returns a list of all the keys for a given file.

```
keys ey
```

The # operation gives the number of entries.

```
#ey
```

The table view of keyed access files provides safe operations. That is, if the Axiom program is terminated between file operations, the file is left in a consistent, current state. This means, however, that the operations are somewhat costly. For example, after each update the file is closed.

Here we add several more items to the file, then check its contents.

```
KE := Record(key: String, entry: Integer)
```

```
reopen!(ey, "output")
```

If many items are to be added to a file at the same time, then it is more efficient to use the write operation.

```
write!(ey, ["van Hulzen", 1983]$KE)
```

```
write!(ey, ["Calmet", 1982]$KE)
```

```
write!(ey, ["Wang", 1981]$KE)
```

```
close! ey
```

The read operation is also available from the file view, but it returns elements in a random order. It is generally clearer and more efficient to use the keys operation and to extract elements by key.

— domain KAFfile KeyedAccessFile —

```

)abbrev domain KAFfile KeyedAccessFile
++ Author: Stephen M. Watt
++ Date Created: 1985
++ Date Last Updated: June 4, 1991
++ Description:
++ This domain allows a random access file to be viewed both as a table
++ and as a file object. The KeyedAccessFile format is a directory
++ containing a single file called "index.kaf". This file is a random
++ access file. The first thing in the file is an integer which is the
++ byte offset of an association list (the dictionary) at the end of
++ the file. The association list is of the form
++ ((key . byteoffset) (key . byteoffset)...)
++ where the byte offset is the number of bytes from the beginning of
++ the file. This offset contains an s-expression for the value of the key.

KeyedAccessFile(Entry): KAFcategory == KAFcapsule where
  Name ==> FileName
  Key ==> String
  Entry : SetCategory

KAFcategory ==
  Join(FileCategory(Name, Record(key: Key, entry: Entry)),
        TableAggregate(Key, Entry)) with
        finiteAggregate
        pack_!: % -> %
        ++ pack!(f) reorganizes the file f on disk to recover
        ++ unused space.

KAFcapsule == add

CLASS ==> 131 -- an arbitrary no. greater than 127

```

```

=====
Library examples
=====

```

The Library domain provides a simple way to store Axiom values in a file. This domain is similar to KeyedAccessFile but fewer declarations are needed and items of different types can be saved together in the same file.

To create a library, you supply a file name.

```
stuff := library "Neat.stuff"
```

Now values can be saved by key in the file. The keys should be mnemonic, just as the field names are for records. They can be given either as strings or symbols.

```
stuff.int := 32**2

stuff."poly" := x**2 + 1

stuff.str := "Hello"
```

You obtain the set of available keys using the keys operation.

```
keys stuff
```

You extract values by giving the desired key in this way.

```
stuff.poly
```

```
stuff("poly")
```

When the file is no longer needed, you should remove it from the file system.

```
)system rm -rf Neat.stuff
```

)abbrev domain LIB Library
++ Author: Stephen M. Watt
++ Date Created: 1985
++ Date Last Updated: June 4, 1991
++ Description:
++ This domain provides a simple way to save values in files.

Library(): TableAggregate(String, Any) with
  library: FileName -> %
    ++ library(ln) creates a new library file.
  pack_!: % -> %
    ++ pack!(f) reorganizes the file f on disk to recover
    ++ unused space.

  elt : (%, Symbol) -> Any
    ++ elt(lib,k) or lib.k extracts the value corresponding to
    ++ the key \spad{k} from the library \spad{lib}.

  setelt : (%, Symbol, Any) -> Any
    ++ \spad{lib.k := v} saves the value \spad{v} in the library
    ++ \spad{lib}. It can later be extracted using the key \spad{k}.

  close_!: % -> %
    ++ close!(f) returns the library f closed to input and output.

== KeyedAccessFile(Any) add
  Rep := KeyedAccessFile(Any)
  library f == open f
  elt(f:%,v:Symbol) == elt(f, string v)
  setelt(f:%, v:Symbol, val:Any) == setelt(f, string v, val)

```

LieSquareMatrix(n,R) implements the Lie algebra of the n by n matrices over the commutative ring R.

The Lie bracket (commutator) of the algebra is given by

$$a*b := (a *\$SQMATRIX(n,R) b - b *\$SQMATRIX(n,R) a)$$

where *\\$SQMATRIX(n,R) is the usual matrix multiplication.

)abbrev domain LSQM LieSquareMatrix
++ Author: J. Grabmeier
++ Date Created: 07 March 1991
++ Date Last Updated: 08 March 1991
++ Description:
++ LieSquareMatrix(n,R) implements the Lie algebra of the n by n
++ matrices over the commutative ring R.
++ The Lie bracket (commutator) of the algebra is given by\br
++ \spad{a*b := (a *$$SQMATRIX(n,R) b - b *$$SQMATRIX(n,R) a)},\br
++ where \spadfun{*$SQMATRIX(n,R)} is the usual matrix multiplication.

LieSquareMatrix(n,R): Exports == Implementation where

 LinearOrdinaryDifferentialOperator examples
 =====

LinearOrdinaryDifferentialOperator(A, diff) is the domain of linear ordinary differential operators with coefficients in a ring A with a given derivation.

=====
 Differential Operators with Series Coefficients
 =====

Problem:

Find the first few coefficients of $\exp(x)/x^i$ of Dop phi where

Dop := D³ + G/x² * D + H/x³ - 1
 phi := sum(s[i]*exp(x)/xⁱ, i = 0..)

Solution:

Define the differential.

Dx: LODO(EXPR INT, f +-> D(f, x))
 Type: Void

Dx := D()
 D
 Type: LinearOrdinaryDifferentialOperator(Expression Integer,
 theMap LAMBDA-CLOSURE(NIL,NIL,NIL,G1404 envArg,
 SPADCALL(G1404,QUOTE x,
 ELT(*1;anonymousFunction;0;frame0;internal;MV,0)))

Now define the differential operator Dop.

Dop:= Dx³ + G/x²*Dx + H/x³ - 1

$$D + \frac{G}{x^2} D + \frac{-x + H}{x^3}$$

 Type: LinearOrdinaryDifferentialOperator(Expression Integer,
 theMap LAMBDA-CLOSURE(NIL,NIL,NIL,G1404 envArg,

```

SPADCALL(G1404,QUOTE x,
          ELT(*1;anonymousFunction;0;frame0;internal;MV,0)))

=====
LinearOrdinaryDifferentialOperator1 example
=====

```

LinearOrdinaryDifferentialOperator1(A) is the domain of linear ordinary differential operators with coefficients in the differential ring A.

```

=====
Differential Operators with Rational Function Coefficients
=====

```

This example shows differential operators with rational function coefficients. In this case operator multiplication is non-commutative and, since the coefficients form a field, an operator division algorithm exists.

We begin by defining RFZ to be the rational functions in x with integer coefficients and Dx to be the differential operator for d/dx .

```

RFZ := Fraction UnivariatePolynomial('x, Integer)
      Fraction UnivariatePolynomial(x,Integer)
      Type: Domain

x : RFZ := 'x
  x
      Type: Fraction UnivariatePolynomial(x,Integer)

Dx : LOD01 RFZ := D()
  D
      Type: LinearOrdinaryDifferentialOperator1
      Fraction UnivariatePolynomial(x,Integer)

```

Operators are created using the usual arithmetic operations.

```

b : LOD01 RFZ := 3*x**2*Dx**2 + 2*Dx + 1/x
      2 2      1
      3x D  + 2D + -
                x
                                Type: LinearOrdinaryDifferentialOperator1
                                Fraction UnivariatePolynomial(x,Integer)
    
```

```

a : LOD01 RFZ := b*(5*x*Dx + 7)
      3 3      2      2      7
      15x D  + (51x  + 10x)D  + 29D + -
                x
                                Type: LinearOrdinaryDifferentialOperator1
                                Fraction UnivariatePolynomial(x,Integer)
    
```

Operator multiplication corresponds to functional composition.

```

p := x**2 + 1/x**2
      4
      x  + 1
      -----
      2
      x
                                Type: Fraction UnivariatePolynomial(x,Integer)
    
```

Since operator coefficients depend on x, the multiplication is not commutative.

```

(a*b - b*a) p
      4
      - 75x  + 540x - 75
      -----
      4
      x
                                Type: Fraction UnivariatePolynomial(x,Integer)
    
```

When the coefficients of operator polynomials come from a field, as in this case, it is possible to define operator division. Division on the left and division on the right yield different results when the multiplication is non-commutative.

The results of leftDivide and rightDivide are quotient-remainder pairs satisfying:

$$\begin{aligned} \text{leftDivide}(a,b) &= [q, r] \text{ such that } a = b*q + r \\ \text{rightDivide}(a,b) &= [q, r] \text{ such that } a = q*b + r \end{aligned}$$

In both cases, the degree of the remainder, r, is less than the degree of b.

```
ld := leftDivide(a,b)
```

```
[quotient= 5x D + 7,remainder= 0]
  Type: Record(quotient: LinearOrdinaryDifferentialOperator1
               Fraction UnivariatePolynomial(x,Integer),
               remainder: LinearOrdinaryDifferentialOperator1
               Fraction UnivariatePolynomial(x,Integer))

a = b * ld.quotient + ld.remainder
  3 3      2      2      7      3 3      2      2      7
15x D + (51x + 10x)D + 29D + -= 15x D + (51x + 10x)D + 29D + -
  Type: Equation LinearOrdinaryDifferentialOperator1
               Fraction UnivariatePolynomial(x,Integer)
```

The operations of left and right division are so-called because the quotient is obtained by dividing a on that side by b.

```
rd := rightDivide(a,b)
[quotient= 5x D + 7,remainder= 10D + -]
  Type: Record(quotient: LinearOrdinaryDifferentialOperator1
               Fraction UnivariatePolynomial(x,Integer),
               remainder: LinearOrdinaryDifferentialOperator1
               Fraction UnivariatePolynomial(x,Integer))

a = rd.quotient * b + rd.remainder
  3 3      2      2      7      3 3      2      2      7
15x D + (51x + 10x)D + 29D + -= 15x D + (51x + 10x)D + 29D + -
  Type: Equation LinearOrdinaryDifferentialOperator1
               Fraction UnivariatePolynomial(x,Integer)
```

Operations `rightQuotient` and `rightRemainder` are available if only one of the quotient or remainder are of interest to you. This is the quotient from right division.

```
rightQuotient(a,b)
  5x D + 7
  Type: LinearOrdinaryDifferentialOperator1
        Fraction UnivariatePolynomial(x,Integer)
```

This is the remainder from right division. The corresponding "left" functions, `leftQuotient` and `leftRemainder` are also available.

```
rightRemainder(a,b)
  5
10D + -
  x
  Type: LinearOrdinaryDifferentialOperator1
        Fraction UnivariatePolynomial(x,Integer)
```

For exact division, operations `leftExactQuotient` and `rightExactQuotient` are supplied. These return the quotient but only if the remainder is zero. The call `rightExactQuotient(a,b)` would yield an error.

```
leftExactQuotient(a,b)
  5x D + 7
  Type: Union(LinearOrdinaryDifferentialOperator1
              Fraction UnivariatePolynomial(x,Integer),...)
```

The division operations allow the computation of left and right greatest common divisors, leftGcd and rightGcd via remainder sequences, and consequently the computation of left and right least common multiples, rightLcm and leftLcm.

```
e := leftGcd(a,b)
  2 2      1
  3x D + 2D + -
                x
  Type: LinearOrdinaryDifferentialOperator1
        Fraction UnivariatePolynomial(x,Integer)
```

Note that a greatest common divisor doesn't necessarily divide a and b on both sides. Here the left greatest common divisor does not divide a on the right.

```
leftRemainder(a, e)
  0
  Type: LinearOrdinaryDifferentialOperator1
        Fraction UnivariatePolynomial(x,Integer)
```

```
rightRemainder(a, e)
  5
  10D + -
        x
  Type: LinearOrdinaryDifferentialOperator1
        Fraction UnivariatePolynomial(x,Integer)
```

Similarly, a least common multiple is not necessarily divisible from both sides.

```
f := rightLcm(a,b)
  3 3      2      2      7
  15x D + (51x + 10x)D + 29D + -
  Type: LinearOrdinaryDifferentialOperator1
        Fraction UnivariatePolynomial(x,Integer)
```

```
rightRemainder(f, b)
  5
  10D + -
        x
  Type: LinearOrdinaryDifferentialOperator1
        Fraction UnivariatePolynomial(x,Integer)
```

```

leftRemainder(f, b)
0
Type: LinearOrdinaryDifferentialOperator1
      Fraction UnivariatePolynomial(x,Integer)

```

— domain LODO1 LinearOrdinaryDifferentialOperator1 —

```

)abbrev domain LODO1 LinearOrdinaryDifferentialOperator1
++ Author: Manuel Bronstein
++ Date Created: 9 December 1993
++ Date Last Updated: 31 January 1994
++ Description:
++ \spad{LinearOrdinaryDifferentialOperator1} defines a ring of
++ differential operators with coefficients in a differential ring A.
++ Multiplication of operators corresponds to functional composition:\br
++ \spad{(L1 * L2).(f) = L1 L2 f}

```

```

=====
LinearOrdinaryDifferentialOperator2
=====

```

LinearOrdinaryDifferentialOperator2(A, M) is the domain of linear ordinary differential operators with coefficients in the differential ring A and operating on M, an A-module. This includes the cases of operators which are polynomials in D acting upon scalar or vector expressions of a single variable. The coefficients of the operator polynomials can be integers, rational functions, matrices or elements of other domains.

```

=====
Differential Operators with Constant Coefficients
=====

```

This example shows differential operators with rational number coefficients operating on univariate polynomials.

We begin by making type assignments so we can conveniently refer to univariate polynomials in x over the rationals.

```
Q := Fraction Integer
  Fraction Integer
      Type: Domain
```

```
PQ := UnivariatePolynomial('x, Q)
  UnivariatePolynomial(x, Fraction Integer)
      Type: Domain
```

```
x: PQ := 'x
  x
      Type: UnivariatePolynomial(x, Fraction Integer)
```

Now we assign Dx to be the differential operator D corresponding to d/dx.

```
Dx: LODO2(Q, PQ) := D()
  D
      Type: LinearOrdinaryDifferentialOperator2(Fraction Integer,
          UnivariatePolynomial(x, Fraction Integer))
```

New operators are created as polynomials in D().

```
a := Dx + 1
  D + 1
      Type: LinearOrdinaryDifferentialOperator2(Fraction Integer,
          UnivariatePolynomial(x, Fraction Integer))
```

```
b := a + 1/2*Dx**2 - 1/2
  1 2      1
  - D + D + -
  2          2
      Type: LinearOrdinaryDifferentialOperator2(Fraction Integer,
          UnivariatePolynomial(x, Fraction Integer))
```

To apply the operator a to the value p the usual function call syntax is used.

```
p := 4*x**2 + 2/3
  2 2
  4x + -
      3
      Type: UnivariatePolynomial(x, Fraction Integer)
```

```
a p
  2 2
  4x + 8x + -
      3
      Type: UnivariatePolynomial(x, Fraction Integer)
```

Operator multiplication is defined by the identity (a*b)p = a(b(p))

```
(a * b) p = a b p
      2      37      2      37
2x  + 12x + --- 2x  + 12x + ---
      3      3
Type: Equation UnivariatePolynomial(x,Fraction Integer)
```

Exponentiation follows from multiplication.

```
c := (1/9)*b*(a + b)^2
      1 6   5 5   13 4   19 3   79 2   7   1
-- D + -- D + -- D + -- D + -- D + -- D + -
      72  36  24  18  72  12  8
Type: LinearOrdinaryDifferentialOperator2(Fraction Integer,
UnivariatePolynomial(x,Fraction Integer))
```

Finally, note that operator expressions may be applied directly.

```
(a**2 - 3/4*b + c) (p + 1)
      2  44   541
3x  + -- x + ---
      3    36
Type: UnivariatePolynomial(x,Fraction Integer)
```

```
=====
Differential Operators with Matrix Coefficients Operating on Vectors}
=====
```

This is another example of linear ordinary differential operators with non-commutative multiplication. Unlike the rational function case, the differential ring of square matrices (of a given dimension) with univariate polynomial entries does not form a field. Thus the number of operations available is more limited.

In this section, the operators have three by three matrix coefficients with polynomial entries.

```
PZ := UnivariatePolynomial(x,Integer)
UnivariatePolynomial(x,Integer)
Type: Domain

x:PZ := 'x
x
Type: UnivariatePolynomial(x,Integer)

Mat := SquareMatrix(3,PZ)
SquareMatrix(3,UnivariatePolynomial(x,Integer))
Type: Domain
```

The operators act on the vectors considered as a Mat-module.

```
Vect := DPMM(3, PZ, Mat, PZ)
DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),SquareMatrix(3,UnivariatePolynomial(x,Integer)),UnivariatePolynomial(x,Integer))
Type: Domain
```

```
Modo := LODO2(Mat, Vect)
LinearOrdinaryDifferentialOperator2(SquareMatrix(3,UnivariatePolynomial(x,Integer)),DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),SquareMatrix(3,UnivariatePolynomial(x,Integer)),UnivariatePolynomial(x,Integer)))
Type: Domain
```

The matrix m is used as a coefficient and the vectors p and q are operated upon.

```
m:Mat := matrix [ [x^2,1,0],[1,x^4,0],[0,0,4*x^2] ]
+ 2 +
|x 1 0 |
| 4 |
|1 x 0 |
| 2|
+0 0 4x +
Type: SquareMatrix(3,UnivariatePolynomial(x,Integer))
```

```
p:Vect := directProduct [3*x^2+1,2*x,7*x^3+2*x]
2 3
[3x + 1,2x,7x + 2x]
Type: DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),
SquareMatrix(3,UnivariatePolynomial(x,Integer)),
UnivariatePolynomial(x,Integer))
```

```
q: Vect := m * p
4 2 5 2 5 3
[3x + x + 2x,2x + 3x + 1,28x + 8x ]
Type: DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),
SquareMatrix(3,UnivariatePolynomial(x,Integer)),
UnivariatePolynomial(x,Integer))
```

Now form a few operators.

```
Dx : Modo := D()
D
Type: LinearOrdinaryDifferentialOperator2(
SquareMatrix(3,UnivariatePolynomial(x,Integer)),
DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),
SquareMatrix(3,UnivariatePolynomial(x,Integer)),
UnivariatePolynomial(x,Integer)))
```

```
a : Modo := Dx + m
```

)abbrev domain LODO2 LinearOrdinaryDifferentialOperator2
++ Author: Stephen M. Watt, Manuel Bronstein
++ Date Created: 1986
++ Date Last Updated: 1 February 1994
++ Description:
++ \spad{LinearOrdinaryDifferentialOperator2} defines a ring of
++ differential operators with coefficients in a differential ring A
++ and acting on an A-module M.
++ Multiplication of operators corresponds to functional composition:\br
++ \spad{(L1 * L2).(f) = L1 L2 f}

LinearOrdinaryDifferentialOperator2(A, M): Exports == Implementation where
  A: DifferentialRing
  M: LeftModule A with
    differentiate: $ -> $
    ++ differentiate(x) returns the derivative of x

Exports ==> Join(LinearOrdinaryDifferentialOperatorCategory A, Eltable(M, M))

Implementation ==> LinearOrdinaryDifferentialOperator(A, differentiate$A) add
elt(p:%, m:M):M ==
  apply(p, differentiate, m)$ApplyUnivariateSkewPolynomial(A, M, %)

=====
List examples
=====

```

A list is a finite collection of elements in a specified order that can contain duplicates. A list is a convenient structure to work with because it is easy to add or remove elements and the length need not be constant. There are many different kinds of lists in Axiom, but the default types (and those used most often) are created by the List constructor. For example, there are objects of type List Integer, List Float and List Polynomial Fraction Integer. Indeed, you can even have List List List Boolean (that is, lists of lists of lists of Boolean values). You can have lists of any type of Axiom object.

```

=====
Creating Lists
=====

```

The easiest way to create a list with, for example, the elements 2, 4, 5, 6 is to enclose the elements with square brackets and separate the elements with commas.

The spaces after the commas are optional, but they do improve the readability.

```

[2, 4, 5, 6]
[2,4,5,6]

```

Type: List PositiveInteger

To create a list with the single element 1, you can use either [1] or the operation list.

```
[1]
  [1]
```

Type: List PositiveInteger

```
list(1)
  [1]
```

Type: List PositiveInteger

Once created, two lists k and m can be concatenated by issuing append(k,m). append does not physically join the lists, but rather produces a new list with the elements coming from the two arguments.

```
append([1,2,3],[5,6,7])
  [1,2,3,5,6,7]
```

Type: List PositiveInteger

Use cons to append an element onto the front of a list.

```
cons(10,[9,8,7])
  [10,9,8,7]
```

Type: List PositiveInteger

=====
Accessing List Elements
=====

To determine whether a list has any elements, use the operation empty?.

```
empty? [x+1]
  false
```

Type: Boolean

Alternatively, equality with the list constant nil can be tested.

```
([] = nil)@Boolean
  true
```

Type: Boolean

We'll use this in some of the following examples.

```
k := [4,3,7,3,8,5,9,2]
  [4,3,7,3,8,5,9,2]
```

Type: List PositiveInteger

Each of the next four expressions extracts the first element of k.

```

first k
  4
                                Type: PositiveInteger

```

```

k.first
  4
                                Type: PositiveInteger

```

```

k.1
  4
                                Type: PositiveInteger

```

```

k(1)
  4
                                Type: PositiveInteger

```

The last two forms generalize to $k.i$ and $k(i)$, respectively, where $1 \leq i \leq n$ and n equals the length of k .

This length is calculated by `#`.

```

n := #k
  8
                                Type: PositiveInteger

```

Performing an operation such as $k.i$ is sometimes referred to as indexing into k or elting into k . The latter phrase comes about because the name of the operation that extracts elements is called `elt`. That is, $k.3$ is just alternative syntax for `elt(k,3)`. It is important to remember that list indices begin with 1. If we issue `k := [1,3,2,9,5]` then $k.4$ returns 9. It is an error to use an index that is not in the range from 1 to the length of the list.

The last element of a list is extracted by any of the following three expressions.

```

last k
  2
                                Type: PositiveInteger

```

```

k.last
  2
                                Type: PositiveInteger

```

This form computes the index of the last element and then extracts the element from the list.

```

k.(#k)
  2

```

Type: PositiveInteger

```
=====
Changing List Elements
=====
```

We'll use this in some of the following examples.

```
k := [4,3,7,3,8,5,9,2]
     [4,3,7,3,8,5,9,2]
```

Type: List PositiveInteger

List elements are reset by using the `k.i` form on the left-hand side of an assignment. This expression resets the first element of `k` to 999.

```
k.1 := 999
     999
```

Type: PositiveInteger

As with indexing into a list, it is an error to use an index that is not within the proper bounds. Here you see that `k` was modified.

```
k
[999,3,7,3,8,5,9,2]
```

Type: List PositiveInteger

The operation that performs the assignment of an element to a particular position in a list is called `setelt`. This operation is destructive in that it changes the list. In the above example, the assignment returned the value 999 and `k` was modified. For this reason, lists are called mutable objects: it is possible to change part of a list (mutate it) rather than always returning a new list reflecting the intended modifications.

Moreover, since lists can share structure, changes to one list can sometimes affect others.

```
k := [1,2]
     [1,2]
```

Type: List PositiveInteger

```
m := cons(0,k)
     [0,1,2]
```

Type: List Integer

Change the second element of `m`.

```
m.2 := 99
     99
```

Type: PositiveInteger

See, m was altered.

```
m
  [0,99,2]
                                Type: List Integer
```

But what about k? It changed too!

```
k
  [99,2]
                                Type: List PositiveInteger
```

```
=====
Other Functions
=====
```

An operation that is used frequently in list processing is that which returns all elements in a list after the first element.

```
k := [1,2,3]
  [1,2,3]
                                Type: List PositiveInteger
```

Use the rest operation to do this.

```
rest k
  [2,3]
                                Type: List PositiveInteger
```

To remove duplicate elements in a list k, use removeDuplicates.

```
removeDuplicates [4,3,4,3,5,3,4]
  [4,3,5]
                                Type: List PositiveInteger
```

To get a list with elements in the order opposite to those in a list k, use reverse.

```
reverse [1,2,3,4,5,6]
  [6,5,4,3,2,1]
                                Type: List PositiveInteger
```

To test whether an element is in a list, use member?: member?(a,k) returns true or false depending on whether a is in k or not.

```
member?(1/2, [3/4,5/6,1/2])
  true
                                Type: Boolean
```

```
member?(1/12, [3/4, 5/6, 1/2])
false
```

Type: Boolean

We can get a list containing all but the last of the elements in a given non-empty list `k`.

```
reverse(rest(reverse(k)))
[1,2]
```

Type: List PositiveInteger

```
=====  
Dot, Dot  
=====
```

Certain lists are used so often that Axiom provides an easy way of constructing them. If `n` and `m` are integers, then `expand [n..m]` creates a list containing `n`, `n+1`, ... `m`. If `n > m` then the list is empty. It is actually permissible to leave off the `m` in the dot-dot construction (see below).

The dot-dot notation can be used more than once in a list construction and with specific elements being given. Items separated by dots are called segments.

```
[1..3,10,20..23]
[1..3,10..10,20..23]
```

Type: List Segment PositiveInteger

Segments can be expanded into the range of items between the endpoints by using `expand`.

```
expand [1..3,10,20..23]
[1,2,3,10,20,21,22,23]
```

Type: List Integer

What happens if we leave off a number on the right-hand side of `..`?

```
expand [1..]
[1,2,3,4,5,6,7,8,9,10,...]
```

Type: Stream Integer

What is created in this case is a Stream which is a generalization of a list.

)abbrev domain LIST List
++ Author: Michael Monagan
++ Date Created: Sep 1987
++ Description:
++ \spadtype{List} implements singly-linked lists that are
++ addressable by indices; the index of the first element
++ is 1. In addition to the operations provided by
++ \spadtype{IndexedList}, this constructor provides some
++ LISP-like functions such as \spadfun{null} and \spadfun{cons}.

List(S:Type): Exports == Implementation where
LISTMININDEX ==> 1      -- this is the minimum list index

Exports ==> ListAggregate S with
nil          : ()      -> %
  ++ nil() returns the empty list.
null         : %       -> Boolean
  ++ null(u) tests if list \spad{u} is the
  ++ empty list.
cons         : (S, %) -> %
  ++ cons(element,u) appends \spad{element} onto the front
  ++ of list \spad{u} and returns the new list. This new list
  ++ and the old one will share some structure.
append      : (%, %) -> %
  ++ append(u1,u2) appends the elements of list \spad{u1}
  ++ onto the front of list \spad{u2}. This new list
  ++ and \spad{u2} will share some structure.
if S has SetCategory then
  setUnion   : (%, %) -> %
  ++ setUnion(u1,u2) appends the two lists u1 and u2, then
  ++ removes all duplicates. The order of elements in the
  ++ resulting list is unspecified.
  setIntersection : (%, %) -> %
  ++ setIntersection(u1,u2) returns a list of the elements
  ++ that lists \spad{u1} and \spad{u2} have in common.
  ++ The order of elements in the resulting list is unspecified.
  setDifference : (%, %) -> %
  ++ setDifference(u1,u2) returns a list of the elements
  ++ of \spad{u1} that are not also in \spad{u2}.
  ++ The order of elements in the resulting list is unspecified.
if S has OpenMath then OpenMath

Implementation ==>

— domain LMOPS ListMonoidOps —

```

)abbrev domain LMOPS ListMonoidOps
++ Author: Manuel Bronstein
++ Date Created: November 1989
++ Date Last Updated: 6 June 1991
++ Description:
++ This internal package represents monoid (abelian or not, with or
++ without inverses) as lists and provides some common operations
++ to the various flavors of monoids.
  
```

```
ListMonoidOps(S, E, un): Exports == Implementation where
```

```

S : SetCategory
E : AbelianMonoid
un: E
  
```

```
REC ==> Record(gen:S, exp: E)
```

```
0 ==> OutputForm
```

```
Exports ==> Join(SetCategory, RetractableTo S) with
```

```

outputForm : ($, (0, 0) -> 0, (0, 0) -> 0, Integer) -> 0
  
```

```

++ outputForm(l, fop, fexp, unit) converts the monoid element
++ represented by l to an \spadtype{OutputForm}.
++ Argument unit is the output form
++ for the \spadignore{unit} of the monoid (e.g. 0 or 1),
++ \spad{fop(a, b)} is the
++ output form for the monoid operation applied to \spad{a} and b
++ (e.g. \spad{a + b}, \spad{a * b}, \spad{ab}),
++ and \spad{fexp(a, n)} is the output form
++ for the exponentiation operation applied to \spad{a} and n
++ (e.g. \spad{n a}, \spad{n * a}, \spad{a ** n}, \spad{a^~n}).
listOfMonoms : $ -> List REC
++ listOfMonoms(l) returns the list of the monomials forming l.
makeTerm      : (S, E) -> $
++ makeTerm(s, e) returns the monomial s exponentiated by e
++ (e.g. s^e or e * s).
makeMulti     : List REC -> $
++ makeMulti(l) returns the element whose list of monomials is l.
nthExpon      : ($, Integer) -> E
++ nthExpon(l, n) returns the exponent of the n^th monomial of l.
nthFactor     : ($, Integer) -> S
++ nthFactor(l, n) returns the factor of the n^th monomial of l.
reverse       : $ -> $
++ reverse(l) reverses the list of monomials forming l. This
++ has some effect if the monoid is non-abelian, i.e.
++ \spad{reverse(a1^e1 ... an^en) = an^en ... a1^e1} which is different.
reverse_!     : $ -> $
++ reverse!(l) reverses the list of monomials forming l, destroying
++ the element l.
size          : $ -> NonNegativeInteger
++ size(l) returns the number of monomials forming l.
makeUnit      : () -> $
++ makeUnit() returns the unit element of the monomial.
rightMult     : ($, S) -> $
++ rightMult(a, s) returns \spad{a * s} where \spad{*}
++ is the monoid operation,
++ which is assumed non-commutative.
leftMult      : (S, $) -> $
++ leftMult(s, a) returns \spad{s * a} where
++ \spad{*} is the monoid operation,
++ which is assumed non-commutative.
plus          : (S, E, $) -> $
++ plus(s, e, x) returns \spad{e * s + x} where \spad{+}
++ is the monoid operation,
++ which is assumed commutative.
plus          : ($, $) -> $
++ plus(x, y) returns \spad{x + y} where \spad{+}
++ is the monoid operation,
++ which is assumed commutative.
commutativeEquality: ($, $) -> Boolean
++ commutativeEquality(x,y) returns true if x and y are equal

```

```

    ++ assuming commutativity
mapExpon      : (E -> E, $) -> $
    ++ mapExpon(f, a1\^e1 ... an\^en) returns \spad{a1\^f(e1) ... an\^f(en)}.
mapGen       : (S -> S, $) -> $
    ++ mapGen(f, a1\^e1 ... an\^en) returns \spad{f(a1)\^e1 ... f(an)\^en}.

 ListMultiDictionary examples
 =====

The ListMultiDictionary domain implements a dictionary with duplicates allowed. The representation is a list with duplicates represented explicitly. Hence most operations will be relatively inefficient when the number of entries in the dictionary becomes large. If the objects in the dictionary belong to an ordered set, the entries are maintained in ascending order.

=====
LyndonWord examples
=====

```

A function f in $[0,1]$ is called acyclic if $C(F)$ consists of n different objects. The canonical representative of the orbit of an acyclic function is usually called a Lyndon Word. If f is acyclic, then all elements in the orbit $C(f)$ are acyclic as well, and we call $C(f)$ an acyclic orbit.

++ Author: Michel Petitot (petitot@lifl.fr).
++ Date Created: 91
++ Date Last Updated: 7 Juillet 92
++ Fix History: compilation v 2.1 le 13 dec 98
++ References:
++ Free Lie Algebras by C. Reutenauer (Oxford science publications).
++ Description:
++ Lyndon words over arbitrary (ordered) symbols:
++ see Free Lie Algebras by C. Reutenauer (Oxford science publications).
++ A Lyndon word is a word which is smaller than any of its right factors
```

```

++ w.r.t. the pure lexicographical ordering.
++ If \axiom{a} and \axiom{b} are two Lyndon words such that \axiom{a < b}
++ holds w.r.t lexicographical ordering then \axiom{a*b} is a Lyndon word.
++ Parenthesized Lyndon words can be generated from symbols by using the
++ following rule:\br
++ \axiom{[[a,b],c]} is a Lyndon word iff \axiom{a*b < c <= b} holds.\br
++ Lyndon words are internally represented by binary trees using the
++ \spadtype{Magma} domain constructor.
++ Two ordering are provided: lexicographic and
++ length-lexicographic.

```

```

=====
MathMLFormat examples
=====
```

This package is based on the TeXFormat domain by Robert S. Sutor
 MathMLFormat provides a coercion from OutputForm to MathML format.

See Also:

- o `)show MathMLFormat`

Both this code and documentation are still under development and I don't pretend they are anywhere close to perfect or even finished. However the code does work and I hope it might be useful to somebody both for it's ability to output MathML from Axiom and as an example of how to write a new output form.

Introduction to Mathematical Markup Language

MathML exists in two forms: presentation and content. At this time (2007-02-11) the package only has a presentation package. A content package is in the works however it is more difficult. Unfortunately Axiom does not make its semantics easily available. The `OutputForm` domain mediates between the individual Axiom domains and the user visible output but `OutputForm` does not provide full semantic information. From my currently incomplete understanding of Axiom it appears that remedying this would entail going back to the individual domains and rewriting a lot of code. However some semantics are conveyed directly by `OutputForm` and other things can be deduced from `OutputForm` or from the original user command.

Displaying MathML

The MathML string produced by `)set output mathml on` can be pasted directly into an appropriate xhtml page and then viewed in Firefox or some other MathML aware browser. The boiler plate code needed for a test page, `testmathml.xml`, is:

```
<?xml version="1.0" ?>

<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.1 plus MathML 2.0//EN"
    "http://www.w3.org/Math/DTD/mathml2/xhtml-math11-f.dtd" [
<!ENTITY mathml "http://www.w3.org/1998/Math/MathML">
]>

<html xmlns="http://www.w3.org/1999/xhtml"
    xmlns:xlink="http://www.w3.org/1999/xlink" >

  <head>
    <title>MathML Test </title>
  </head>

  <body>
```

```
</body>
</html>
```

Paste the MathML string into the body element and it should display nicely in Firefox.

Test Cases

Here's a list of test cases that currently format correctly:

1. $(x+y)^{**2}$
2. $\text{integrate}(x^{**x},x)$
3. $\text{integral}(x^{**x},x)$
4. $(5 + \text{sqrt } 63 + \text{sqrt } 847)^{**(1/3)}$
5. $\text{set } [1,2,3]$
6. $\text{multiset } [x \text{ rem } 5 \text{ for } x \text{ in } \text{primes}(2,1000)]$
7. $\text{series}(\sin(a*x),x=0)$
8. $\text{matrix } [[x^{**i} + y^{**j} \text{ for } i \text{ in } 1..10] \text{ for } j \text{ in } 1..10]$
9. $y := \text{operator } 'y \text{ a. } D(y(x,z),[x,x,z,x]) \text{ b. } D(y \ x,x,2)$
10. $x := \text{series } 'x \text{ a. } \sin(1+x)$
11. $\text{series}(1/\log(y),y=1)$
12. $y:\text{UTS}(\text{FLOAT},'z,0) := \exp(z)$
13. a. $c := \text{continuedFraction}(314159/100000)$ b. $c := \text{continuedFraction}(314159/100000)$

The `TeXFormat` domain has the capability to format an object with subscripts, superscripts, presubscripts and presuperscripts however I don't know of any Axiom command that produces such an object. In fact at present I see the case of "SUPERSUB" being used for putting primes in the superscript position to denote ordinary differentiation. I also only see the "SUB" case being used to denote partial derivatives.

)set output mathml on

Making `mathml` appear as output during a normal Axiom session by invoking `)set output mathml on` proved to be a bit tedious and seems to be undocumented. I document my experience here in case it proves useful to somebody else trying to get a new output format from Axiom.

In `MathMLFormat` the functions `coerce(expr : OutputForm) : String` and `display(s : String) : Void` provide the desired `mathml` output. Note that this package was constructed by close examination of Robert Sutor's `TeXFormat` domain and much remains from that source. To have `mathml` displayed as output we need to get Axiom to call `display(coerce(expr))` at the appropriate place. Here's what I did to get that to happen. Note

that my starting point here was an attempt by Andrey Grozin to do the same. To figure things out I searched through files for "tex" to see what was done for the `TeXFormat` domain, and used `grep` to find which files had mention of `TeXFormat`.

File `src/interp/setvars.boot.pamphlet`

Create an output `mathml` section by analogy to the `tex` section. Remember to add the code chunk "outputmathmlCode" at the end.

`setvars.boot` is a bootstrap file which means that it has to be precompiled into lisp code and then that code has to be inserted back into `setvars.boot`. To do this extract the boot code by running "notangle" on it. I did this from the "tmp" directory. From inside axiom run ")lisp (boottran::boottocl "tmp/setvars.boot")" which put "setvars.clisp" into "int/interp/setvars.clisp". Then replace the lisp in "setvars.boot.pamphlet" with that in the newly generated "setvars.clisp".

The relevant code chunks appearing in "setvars.boot.pamphlet" are:

```
outputmathmlCode
setOutputMathml
describeSetOutputMathml
```

and the relevant variables are:

```
setOutputMathml
$mathmlOutputStream
$mathmlOutputFile
$mathmlFormat
describeSetOutputMathml
```

File `setvar.boot.pamphlet`

Create an output `mathml` section in "setvar.boot.pamphlet" again patterned after the `tex` section. I changed the default file extension from ".stex" to ".smml".

To the "sectionoutput" table I added the line

```
mathml                created output in MathML style        Off:CONSOLE
```

Added the code chunk "outputmathml" to the code chunk "output" in "sectionoutput".

Relevant code chunks:

```
outputmathml
```

Relevant variables:

```
setOutputMathml
$mathmlFormat
$mathmlOutputFile
```

Note when copying the tex stuff I changed occurrences of "tex" to "mathml", "Tex" to "Mathml" and "TeX" to "MathML".

File src/algebra/Makefile.pamphlet

The file "src/algebra/tex.spad.pamphlet" contains the domain `TexFormat` (TEX) and the package `TexFormat1` (TEX1). However the sole function of `TexFormat1` is to **coerce** objects from a domain into `OutputForm` and then apply `TexFormat` to them. It is to save programmers the trouble of doing the coercion themselves from inside spad code. It does not appear to be used for the main purpose of delivering Axiom output in TeX format. In order to keep the mathml package as simple as possible, and because I didn't see much use for this, I didn't copy the `TexFormat1` package. So no analog of the TEX1 entries in "Makefile.pamphlet" were needed. One curiosity I don't understand is why TEX1 appears in layer 4 when it seems to depend on TEX which appears in layer 14.

Initially I added "\$OUT/MMLFORM.o" to layer 14 and "mathml.spad.pamphlet" to completed spad files in layer 14. When trying to compile the build failed at MMLFORM. It left "MMLFORM.erlib" in "int/algebra" instead of "MMLFORM.NRLIB" which confused me at first because mathml.spad compiled under a running axiom. By examining the file "obj/tmp/trace" I saw that a new dependency had been introduced, compared to `TexFormat`, with the function `eltName` depending on the domain `FSAGG` in layer 16. So the lines had to be moved from layer 14 to layer 17.

Added appropriate lines to "SPADFILES" and "DOCFILES".

File src/algebra/exposed.lsp.pamphlet

Add the line "(|MathMLFormat| . MMLFORM)"

File src/algebra/Lattice.pamphlet

I don't see that this file is used anywhere but I made the appropriate changes anyway by searching for "TEX" and mimicing everything for MMLFORM.

File src/doc/axiom.bib.pamphlet

Added mathml.spad subsection to "src/doc/axiom.bib.pamphlet".

File interp/i-output.boot.pamphlet

This is where the **coerce** and **display** functions from `MathMLFormat` actually get called. The following was added:

```
mathmlFormat expr ==
```

```

mml := '(MathMLFormat)
mmlrep := '(String)
formatFn := getFunctionFromDomain("coerce",mml,[$OutputForm])
displayFn := getFunctionFromDomain("display",mml,[mmlrep])
SPADCALL(SPADCALL(expr,formatFn),displayFn)
TERPRI $mathmlOutputStream
FORCE_-OUTPUT $mathmlOutputStream
NIL

```

Note that compared to the `texFormat` function there are a couple of differences. Since `MathMLFormat` is currently a package rather than a domain there is the "mmlrep" variable whereas in `texFormat` the argument of the "display" function is an instance of the domain. Also the `coerce` function here only has one argument, namely "\$OutputForm".

Also for the function "output(expr,domain)" add lines for mathml, e.g. "if \$mathmlFormat then mathmlFormat expr".

After these changes Axiom compiled with mathml enabled under)set output.

Public Declarations

The declarations

```

E      ==> OutputForm
I      ==> Integer
L      ==> List
S      ==> String
US     ==> UniversalSegment(Integer)

```

provide abbreviations for domains used heavily in the code. The publicly exposed functions are:

coerce: **E** -> **S** This function is the main one for converting an expression in domain `OutputForm` into a MathML string.

coerceS: **E** -> **S** This function is for use from the command line. It converts an `OutputForm` expression into a MathML string and does some formatting so that the output is not one long line. If you take the output from this function, stick it in an emacs buffer in `nxml-mode` and then indent according to mode, you'll get something that's nicer to look at than what comes from `coerce`. Note that `coerceS` returns the same value as `coerce` but invokes a display function as well so that the result will be printed twice in different formats. The need for this is that the output from `coerce` is automatically formatted with line breaks by Axiom's output routine that are not in the right place.

coerceL: **E** -> **S** Similar to `coerceS` except that the displayed result is the MathML string in one long line. These functions can be used, for instance, to get the MathML for the previous result by typing `coerceL(`

expres: **E** -> **S** Converts `OutputForm` to `String` with the structure preserved with braces. This is useful in developing this package. Actually this is not quite accurate. The function

precondition is first applied to the `OutputForm` expression before **expres**. Raw `OutputForm` and the nature of the **precondition** function is still obscure to me at the time of this writing (2007-02-14), however I probably need to understand it to make sure I'm not missing any semantics. The `spad` function **precondition** is just a wrapper for the `lisp` function `outputTran$Lisp`, which I guess is compiled from `boot`.

display: S -> Void This one prints the string returned by `coerce` as one long line, adding "math" tags: `$...$`. Thus the output from this can be stuck directly into an appropriate `html/xhtml` page and will be displayed nicely by a `MathML` aware browser.

displayF: S -> Void This function doesn't exist yet but it would be nice to have a humanly readable formatted output as well. The basics do exist in the `coerceS` function however the formatting still needs some work to be really good.

— public declarations —

```
)abbrev domain MMLFORM MathMLFormat
++ Author: Arthur C. Ralfs
++ Date: January 2007
++ Description:
++ This package is based on the TeXFormat domain by Robert S. Sutor
++ \spadtype{MathMLFormat} provides a coercion from \spadtype{OutputForm}
++ to MathML format.

MathMLFormat(): public == private where
E      ==> OutputForm
I      ==> Integer
L      ==> List
S      ==> String
US     ==> UniversalSegment(Integer)

public == SetCategory with
coerce:  E -> S
  ++ coerceS(o) changes o in the standard output format to MathML
  ++ format.
coerceS: E -> S
  ++ coerceS(o) changes o in the standard output format to MathML
  ++ format and displays formatted result.
coerceL: E -> S
  ++ coerceS(o) changes o in the standard output format to MathML
  ++ format and displays result as one long string.
expres:  E -> S
  ++ covertS \spadtype{OutputForm} to \spadtype{String} with the
  ++ structure preserved with braces. Actually this is not quite
  ++ accurate. The function \spadfun{precondition} is first
  ++ applied to the
  ++ \spadtype{OutputForm} expression before \spadfun{expres}.
  ++ The raw \spadtype{OutputForm} and
  ++ the nature of the \spadfun{precondition} function is
  ++ still obscure to me
```

```

++ at the time of this writing (2007-02-14).
display: S -> Void
++ prints the string returned by coerce, adding <math ...> tags.

```

Private Function Declarations

These are the local functions:

addBraces:S -> S

addBrackets:S -> S

atomize:E -> L E

displayElt:S -> Void function for recursively displaying mathml nicely formatted

eltLimit:(S,I,S) -> I demarcates end position of mathml element with name:S starting at position i:I in mathml string s:S and returns end of end tag as i:I position in mathml string, i.e. find start and end of substring: <name ...>...</name>

eltName:(I,S) -> S find name of mathml element starting at position i:I in string s:S

group:S -> S

formatBinary:(S,L E, I) -> S

formatFunction:(S,L E, I) -> S

formatMatrix:L E -> S

formatNary:(S,L E, I) -> S

formatNaryNoGroup:(S,L E, I) -> S

formatNullary:S -> S

formatPlex:(S,L E, I) -> S

formatSpecial:(S,L E, I) -> S

formatUnary:(S, E, I) -> S

formatMml:(E,I) -> S

newWithNum:I -> \$ this is a relic from tex.spad and is not used here so far. I'll probably

remove it.

parenthesize:S -> S

precondition:E -> E this function is applied to the OutputForm expression before doing anything else.

postcondition:S -> S this function is applied after all other OutputForm -> MathML transformations. In the TexFormat domain the ungroup function first peels off the outermost set of braces however I have replaced braces with <mrow>s here and sometimes the outermost set of <mrow>s is necessary to get proper display in Firefox. For instance with getting the correct size of brackets on a matrix the whole expression needs to be enclosed in a mrow element. It also checks for +- and removes the +.

stringify:E -> S

tagEnd:(S,I,S) -> I finds closing ">" of start or end tag for mathML element for formatting MathML string for human readability. No analog in TexFormat.

ungroup:S -> S

— private function declarations —

-- local function signatures

```

Public Function Definitions

Note that I use the function `sayTeX$Lisp` much as I would `printf` in a C program. I've noticed in grepping the code that there are other "say" functions, `sayBrightly` and `sayMessage` for instance, but I have no idea what the difference is between them at this point. `sayTeX$Lisp` does the job so for the time being I'll use that until I learn more.

The functions `coerceS` and `coerceL` should probably be changed to display functions, *i.e.* **`displayS`** and **`displayL`**, returning `Void`. I really only need the one `coerce` function.

— public function definitions —

Formatting Functions

Still need to format $\backslash\text{zag}$ in `formatSpecial`!

In `formatPlex` the case `op = "INTSIGN"` is now passed off to `formatIntSign` which is a change from the `TexFormat` domain. This is done here for presentation mark up to replace the ugly bound variable that Axiom delivers. For content mark up this has to be done anyway.

The `formatPlex` function also allows for `op = "INDEFINTEGRAL"`. However I don't know what Axiom command gives rise to this case. The `INTSIGN` case already allows for both definite and indefinite integrals.

In the function `formatSpecial` various cases are handled including `SUB` and `SUPERSUB`.

These cases are now caught in `formatMml` and so the code in `formatSpecial` doesn't get executed. The only cases I know of using these are partial derivatives for `SUB` and ordinary derivatives or `SUPERSUB` however in `TeXFormat` the capability is there to handle multi-scripts, i.e. an object with subscripts, superscripts, pre-subscripts and pre-superscripts but I am so far unaware of any Axiom command that produces such a multiscripted object.

Another question is how to represent derivatives. At present I have differential notation for partials and prime notation for ordinary derivatives, but it would be nice to allow for different derivative notations in different circumstances, maybe some options to `)set output mathml on`.

Ordinary derivatives are formatted in `formatSuperSub` and there are 2 versions, `formatSuperSub` and `formatSuperSub1`, which at this point have to be switched by swapping names.

```
=====
MathMLFormat examples
=====
```

MathML is an HTML-like markup language for mathematics. It uses the "knuckle" syntax of HTML such as "<mo>" to introduce a math operator and "</mo>" to mark the end of the operator. Axiom can generate MathML output and does so when it communicates to the browser front end.

This output is enabled by

```
)set output mathml on
```

after which you'll see the MathML markup as well as the algebra. Note that you can turn off the algebra output with

```
)set output algebra off
```

but we don't do that here so you can compare the output.

```
1/2
```

```
1/2
```

```
<math xmlns="http://www.w3.org/1998/Math/MathML" mathsize="big"
  display="block">
  <mrow>
    <mn>1</mn>
    <mo>/</mo>
    <mn>2</mn>
  </mrow>
</math>
```

```
1/(x+5)
```

```
1/(x + 5)
```

```
<math xmlns="http://www.w3.org/1998/Math/MathML" mathsize="big"
  display="block">
  <mrow>
    <mn>1</mn>
  </mrow>
```

```

<mo>/</mo>
<mrow>
  <mo>(</mo>
  <mi>x</mi>
  <mo>+</mo>
  <mn>5</mn>
  <mo>)</mo>
</mrow>
</mrow>
</math>

```

$(x+3)/(y-5)$

$(x + 3)/(y - 5)$

```

<math xmlns="http://www.w3.org/1998/Math/MathML" mathsize="big"
  display="block">
<mrow>
  <mrow>
    <mo>(</mo>
    <mi>x</mi>
    <mo>+</mo>
    <mn>3</mn>
    <mo>)</mo>
  </mrow>
  <mo>/</mo>
  <mrow>
    <mo>(</mo>
    <mi>y</mi>
    <mo>-</mo>
    <mn>5</mn>
    <mo>)</mo>
  </mrow>
</mrow>
R</math>

```
=====
Matrix examples
=====
```

The Matrix domain provides arithmetic operations on matrices and standard functions from linear algebra. This domain is similar to the TwoDimensionalArray domain, except that the entries for Matrix must belong to a Ring.

```
=====
Creating Matrices
=====
```

There are many ways to create a matrix from a collection of values or from existing matrices.

If the matrix has almost all items equal to the same value, use new to create a matrix filled with that value and then reset the entries that are different.

```
m : Matrix(Integer) := new(3,3,0)
+0  0  0+
|    |
|0  0  0|
|    |
+0  0  0+
```

Type: Matrix Integer

To change the entry in the second row, third column to 5, use setelt.

```
setelt(m,2,3,5)
5
```

Type: PositiveInteger

An alternative syntax is to use assignment.

```
m(1,2) := 10
10
```

Type: PositiveInteger

The matrix was destructively modified.

```
m
+0 10 0+
|      |
|0 0 5|
|      |
+0 0 0+
Type: Matrix Integer
```

If you already have the matrix entries as a list of lists, use matrix.

```
matrix [ [1,2,3,4],[0,9,8,7] ]
+1 2 3 4+
|      |
+0 9 8 7+
Type: Matrix Integer
```

If the matrix is diagonal, use diagonalMatrix.

```
dm := diagonalMatrix [1,x**2,x**3,x**4,x**5]
+1 0 0 0 0+
|      |
|  2    |
|0 x 0 0 0|
|      |
|      3  |
|0 0 x 0 0|
|      |
|      4  |
|0 0 0 x 0|
|      |
|      5  |
+0 0 0 0 x+
Type: Matrix Polynomial Integer
```

Use setRow and setColumn to change a row or column of a matrix.

```
setRow!(dm,5,vector [1,1,1,1,1])
+1 0 0 0 0+
|      |
|  2    |
|0 x 0 0 0|
|      |
|      3  |
|0 0 x 0 0|
|      |
|      4  |
|0 0 0 x 0|
|      |
```

```
+1 1 1 1 1+
      Type: Matrix Polynomial Integer
```

```
setColumn!(dm,2,vector [y,y,y,y])
+1 y 0 0 0+
|
|0 y 0 0 0|
|
|          3      |
|0 y x  0 0|
|
|          4      |
|0 y 0  x 0|
|
+1 y 1 1 1 1+
      Type: Matrix Polynomial Integer
```

Use copy to make a copy of a matrix.

```
cdm := copy(dm)
+1 y 0 0 0+
|
|0 y 0 0 0|
|
|          3      |
|0 y x  0 0|
|
|          4      |
|0 y 0  x 0|
|
+1 y 1 1 1 1+
      Type: Matrix Polynomial Integer
```

This is useful if you intend to modify a matrix destructively but want a copy of the original.

```
setelt(dm,4,1,1-x**7)
7
- x + 1
      Type: Polynomial Integer
```

```
[dm,cdm]
+ 1      y 0 0 0+ +1 y 0 0 0+
|      |      | |      |
| 0      y 0 0 0| |0 y 0 0 0|
|      |      | |      |
|          3      | |          3      |
|[ 0      y x  0 0|,|0 y x  0 0|]
|      |      | |      |
| 7          4  | |          4  |
```

```

|- x + 1 y 0 x 0| |0 y 0 x 0|
|          | |          |
+ 1      y 1 1 1+ +1 y 1 1 1+
Type: List Matrix Polynomial Integer

```

Use subMatrix to extract part of an existing matrix. The syntax is subMatrix(m, firstrow, lastrow, firstcol, lastcol).

```

subMatrix(dm,2,3,2,4)
+y 0 0+
|    |
| 3  |
+y x 0+
Type: Matrix Polynomial Integer

```

To change a submatrix, use setsubMatrix.

```

d := diagonalMatrix [1.2,-1.3,1.4,-1.5]
+1.2  0.0  0.0  0.0 +
|          |
|0.0 - 1.3  0.0  0.0 |
|          |
|0.0  0.0  1.4  0.0 |
|          |
+0.0  0.0  0.0 - 1.5+
Type: Matrix Float

```

If e is too big to fit where you specify, an error message is displayed. Use subMatrix to extract part of e, if necessary.

```

e := matrix [ [6.7,9.11],[ -31.33,67.19] ]
+ 6.7  9.11 +
|          |
+- 31.33 67.19+
Type: Matrix Float

```

This changes the submatrix of d whose upper left corner is at the first row and second column and whose size is that of e.

```

setsubMatrix!(d,1,2,e)
+1.2  6.7  9.11  0.0 +
|          |
|0.0 - 31.33 67.19  0.0 |
|          |
|0.0  0.0  1.4  0.0 |
|          |
+0.0  0.0  0.0 - 1.5+
Type: Matrix Float

```

d

```

+1.2    6.7    9.11    0.0 +
|
|0.0 - 31.33  67.19    0.0 |
|
|0.0    0.0    1.4    0.0 |
|
+0.0    0.0    0.0 - 1.5+
Type: Matrix Float

```

Matrices can be joined either horizontally or vertically to make new matrices.

```

a := matrix [ [1/2,1/3,1/4],[1/5,1/6,1/7] ]
+1  1  1+
|-  -  -|
|2  3  4|
|
|1  1  1|
|-  -  -|
+5  6  7+
Type: Matrix Fraction Integer

```

```

b := matrix [ [3/5,3/7,3/11],[3/13,3/17,3/19] ]
+3  3  3+
|-  -  --|
|5  7  11|
|
| 3  3  3|
|-- -- --|
+13 17 19+
Type: Matrix Fraction Integer

```

Use `horizConcat` to append them side to side. The two matrices must have the same number of rows.

```

horizConcat(a,b)
+1  1  1  3  3  3+
|-  -  -  -  -  --|
|2  3  4  5  7  11|
|
|1  1  1  3  3  3|
|-  -  -  -- -- --|
+5  6  7  13 17 19+
Type: Matrix Fraction Integer

```

Use `vertConcat` to stack one upon the other. The two matrices must have the same number of columns.

```

vab := vertConcat(a,b)
+1  1  1 +

```

```

|- - - |
|2 3 4 |
|      |
|1 1 1 |
|- - - |
|5 6 7 |
|      |
|3 3 3|
|- - --|
|5 7 11|
|      |
| 3 3 3|
|-- -- --|
+13 17 19+
    
```

Type: Matrix Fraction Integer

The operation transpose is used to create a new matrix by reflection across the main diagonal.

```

transpose vab
+1 1 3 3+
|- - - --|
|2 5 5 13|
|      |
|1 1 3 3|
|- - - --|
|3 6 7 17|
|      |
|1 1 3 3|
|- - -- --|
+4 7 11 19+
    
```

Type: Matrix Fraction Integer

=====
 Operations on Matrices
 =====

Axiom provides both left and right scalar multiplication.

```

m := matrix [ [1,2],[3,4] ]
+1 2+
|  |
+3 4+
    
```

Type: Matrix Integer

```

4 * m * (-5)
+- 20 - 40+
|      |
+- 60 - 80+
    
```

Type: Matrix Integer

You can add, subtract, and multiply matrices provided, of course, that the matrices have compatible dimensions. If not, an error message is displayed.

```
n := matrix([ [1,0,-2],[ -3,5,1] ])
      + 1  0  - 2+
      |      |
      +- 3  5  1 +
                                     Type: Matrix Integer
```

This following product is defined but $n * m$ is not.

```
m * n
      +- 5  10  0 +
      |      |
      +- 9  20  - 2+
                                     Type: Matrix Integer
```

The operations `nrows` and `ncols` return the number of rows and columns of a matrix. You can extract a row or a column of a matrix using the operations `row` and `column`. The object returned is a `Vector`.

Here is the third column of the matrix `n`.

```
vec := column(n,3)
      [- 2,1]
                                     Type: Vector Integer
```

You can multiply a matrix on the left by a "row vector" and on the right by a "column vector".

```
vec * m
      [1,0]
                                     Type: Vector Integer
```

Of course, the dimensions of the vector and the matrix must be compatible or an error message is returned.

```
m * vec
      [0,- 2]
                                     Type: Vector Integer
```

The operation `inverse` computes the inverse of a matrix if the matrix is invertible, and returns "failed" if not.

This Hilbert matrix is invertible.

```
hilb := matrix([ [1/(i + j) for i in 1..3] for j in 1..3])
      +1  1  1+
```

```

|- - -|
|2 3 4|
|      |
|1 1 1|
|- - -|
|3 4 5|
|      |
|1 1 1|
|- - -|
+4 5 6+

```

Type: Matrix Fraction Integer

```

inverse(hilb)
+ 72 - 240 180 +
|      |
|- 240 900 - 720|
|      |
+ 180 - 720 600 +

```

Type: Union(Matrix Fraction Integer,...)

This matrix is not invertible.

```

mm := matrix([ [1,2,3,4], [5,6,7,8], [9,10,11,12], [13,14,15,16] ])
+1 2 3 4 +
|      |
|5 6 7 8 |
|      |
|9 10 11 12|
|      |
+13 14 15 16+

```

Type: Matrix Integer

```

inverse(mm)
"failed"

```

Type: Union("failed",...)

The operation determinant computes the determinant of a matrix provided that the entries of the matrix belong to a CommutativeRing.

The above matrix mm is not invertible and, hence, must have determinant 0.

```

determinant(mm)
0

```

Type: NonNegativeInteger

The operation trace computes the trace of a square matrix.

```

trace(mm)
34

```

Type: PositiveInteger

The operation `rank` computes the rank of a matrix: the maximal number of linearly independent rows or columns.

```
rank(mm)
2
Type: PositiveInteger
```

The operation `nullity` computes the nullity of a matrix: the dimension of its null space.

```
nullity(mm)
2
Type: PositiveInteger
```

The operation `nullSpace` returns a list containing a basis for the null space of a matrix. Note that the nullity is the number of elements in a basis for the null space.

```
nullSpace(mm)
[[1,- 2,1,0],[2,- 3,0,1]]
Type: List Vector Integer
```

The operation `rowEchelon` returns the row echelon form of a matrix. It is easy to see that the rank of this matrix is two and that its nullity is also two.

```
rowEchelon(mm)
+1 2 3 4 +
|      |
|0 4 8 12|
|      |
|0 0 0 0 |
|      |
+0 0 0 0 +
Type: Matrix Integer
```

— domain MATRIX Matrix —

```
)abbrev domain MATRIX Matrix
++ Author: Grabmeier, Gschnitzer, Williamson
++ Date Created: 1987
++ Date Last Updated: July 1990
++ Description:
++ \spadtype{Matrix} is a matrix domain where 1-based indexing is used
++ for both rows and columns.
```

```
Matrix(R): Exports == Implementation where
  R : Ring
  Row ==> Vector R
```

```

Col ==> Vector R
mnRow ==> 1
mnCol ==> 1
MATLIN ==> MatrixLinearAlgebraFunctions(R,Row,Col,$)
MATSTOR ==> StorageEfficientMatrixOperations(R)

Exports ==> MatrixCategory(R,Row,Col) with
diagonalMatrix: Vector R -> $
  ++ \spad{diagonalMatrix(v)} returns a diagonal matrix where the elements
  ++ of v appear on the diagonal.

if R has ConvertibleTo InputForm then ConvertibleTo InputForm

if R has Field then
inverse: $ -> Union($,"failed")
  ++ \spad{inverse(m)} returns the inverse of the matrix m.
  ++ If the matrix is not invertible, "failed" is returned.
  ++ Error: if the matrix is not square.
-- matrix: Vector Vector R -> $
--   ++ \spad{matrix(v)} converts the vector of vectors v to a matrix, where
--   ++ the vector of vectors is viewed as a vector of the rows of the
--   ++ matrix
-- diagonalMatrix: Vector $ -> $
--   ++ \spad{diagonalMatrix([m1,...,mk])} creates a block diagonal matrix
--   ++ M with block matrices m1,...,mk down the diagonal,
--   ++ with 0 block matrices elsewhere.
-- vectorOfVectors: $ -> Vector Vector R
--   ++ \spad{vectorOfVectors(m)} returns the rows of the matrix m as a
--   ++ vector of vectors

=====
 MonoidRing examples
 =====

MonoidRing(R,M), implements the algebra of all maps from the monoid M to the commutative ring R with finite support.

Multiplication of two maps f and g is defined to map an element c of M to the (convolution) sum over f(a)g(b) such that ab = c. Thus M can be identified with a canonical basis and the maps can also be considered as formal linear combinations of the elements in M. Scalar multiples of a basis element are called monomials. A prominent example is the class of polynomials where the monoid is a direct product of the natural numbers with pointwise addition. When M is FreeMonoid Symbol, one gets polynomials in infinitely many non-commuting variables. Another application area is representation theory of finite groups G, where modules over MonoidRing(R,G) are studied.

++ Description:
++ \spadtype{MonoidRing}(R,M), implements the algebra
++ of all maps from the monoid M to the commutative ring R with
++ finite support.
++ Multiplication of two maps f and g is defined
++ to map an element c of M to the (convolution) sum over f(a)g(b)
++ such that ab = c. Thus M can be identified with a canonical
++ basis and the maps can also be considered as formal linear combinations
++ of the elements in M. Scalar multiples of a basis element are called
++ monomials. A prominent example is the class of polynomials
++ where the monoid is a direct product of the natural numbers
++ with pointwise addition. When M is
++ \spadtype{FreeMonoid Symbol}, one gets polynomials
++ in infinitely many non-commuting variables. Another application
++ area is representation theory of finite groups G, where modules
++ over \spadtype{MonoidRing}(R,G) are studied.

MonoidRing(R: Ring, M: Monoid): MRcategory == MRdefinition where
  Term ==> Record(coef: R, monom: M)

MRcategory ==> Join(Ring, RetractableTo M, RetractableTo R) with
  monomial      : (R, M) -> %
  ++ monomial(r,m) creates a scalar multiple of the basis element m.
  coefficient    : (% , M) -> R
  ++ coefficient(f,m) extracts the coefficient of m in f with respect
  ++ to the canonical basis M.
  coerce:      List Term -> %
  ++ coerce(lt) converts a list of terms and
  ++ coefficients to a member of the domain.
  terms        : % -> List Term
  ++ terms(f) gives the list of non-zero coefficients combined
  ++ with their corresponding basis element as records.
  ++ This is the internal representation.
  map          : (R -> R, %) -> %
  ++ map(fn,u) maps function fn onto the coefficients
  ++ of the non-zero monomials of u.
  monomial?    : % -> Boolean
  ++ monomial?(f) tests if f is a single monomial.
  coefficients: % -> List R
  ++ coefficients(f) lists all non-zero coefficients.
  monomials:   % -> List %
  ++ monomials(f) gives the list of all monomials whose
  ++ sum is f.

```

```

numberOfMonomials: % -> NonNegativeInteger
  ++ numberOfMonomials(f) is the number of non-zero coefficients
  ++ with respect to the canonical basis.
if R has CharacteristicZero then CharacteristicZero
if R has CharacteristicNonZero then CharacteristicNonZero

=====
Multiset examples
=====

```

The domain Multiset(R) is similar to Set(R) except that multiplicities (counts of duplications) are maintained and displayed. Use the operation `multiset` to create multisets from lists. All the standard operations from sets are available for multisets. An element with multiplicity greater than one has the multiplicity displayed first, then a colon, and then the element.

Create a multiset of integers.

```

s := multiset [1,2,3,4,5,4,3,2,3,4,5,6,7,4,10]
      {1,2: 2,3: 3,4: 4,2: 5,6,7,10}
                        Type: Multiset PositiveInteger

```

The operation `insert!` adds an element to a multiset.

```

insert!(3,s)
      {1,2: 2,4: 3,4: 4,2: 5,6,7,10}
                        Type: Multiset PositiveInteger

```

Use `remove!` to remove an element. If a third argument is present, it specifies how many instances to remove. Otherwise all instances of the element are removed. Display the resulting multiset.

```
remove!(3,s,1); s
{1,2: 2,3: 3,4: 4,2: 5,6,7,10}
Type: Multiset PositiveInteger
```

```
remove!(5,s); s
{1,2: 2,3: 3,4: 4,6,7,10}
Type: Multiset PositiveInteger
```

The operation count returns the number of copies of a given value.

```
count(5,s)
0
Type: NonNegativeInteger
```

A second multiset.

```
t := multiset [2,2,2,-9]
{3: 2,- 9}
Type: Multiset Integer
```

The union of two multisets is additive.

```
U := union(s,t)
{1,5: 2,3: 3,4: 4,6,7,10,- 9}
Type: Multiset Integer
```

The intersect operation gives the elements that are in common, with additive multiplicity.

```
I := intersect(s,t)
{5: 2}
Type: Multiset Integer
```

The difference of s and t consists of the elements that s has but t does not. Elements are regarded as indistinguishable, so that if s and t have any element in common, the difference does not contain that element.

```
difference(s,t)
{1,3: 3,4: 4,6,7,10}
Type: Multiset Integer
```

The symmetricDifference is the union of $\text{difference}(s, t)$ and $\text{difference}(t, s)$.

```
S := symmetricDifference(s,t)
{1,3: 3,4: 4,6,7,10,- 9}
Type: Multiset Integer
```

Check that the union of the symmetricDifference and the intersect

equals the union of the elements.

```
(U = union(S,I))@Boolean
true
Type: Boolean
```

Check some inclusion relations.

```
t1 := multiset [1,2,2,3]; [t1 < t, t1 < s, t < s, t1 <= s]
[false,true,false,true]
Type: List Boolean
```

— domain MSET Multiset —

```
)abbrev domain MSET Multiset
++ Author:Stephen M. Watt, William H. Burge, Richard D. Jenks, Frederic Lehobey
++ Date Created:NK
++ Date Last Updated: 14 June 1994
++ Description:
++ A multiset is a set with multiplicities.
```

```
Multiset(S: SetCategory): MultisetAggregate S with
  finiteAggregate
  shallowlyMutable
  multiset: () -> %
    ++ multiset()$D creates an empty multiset of domain D.
  multiset: S -> %
    ++ multiset(s) creates a multiset with singleton s.
  multiset: List S -> %
    ++ multiset(ls) creates a multiset with elements from \spad{ls}.
  members: % -> List S
    ++ members(ms) returns a list of the elements of \spad{ms}
    ++ without their multiplicity. See also \spadfun{parts}.
  remove: (S,%,Integer) -> %
    ++ remove(x,ms,number) removes at most \spad{number} copies of
    ++ element x if \spad{number} is positive, all of them if
    ++ \spad{number} equals zero, and all but at most \spad{-number} if
    ++ \spad{number} is negative.
  remove: ( S -> Boolean ,%,Integer) -> %
    ++ remove(p,ms,number) removes at most \spad{number} copies of
    ++ elements x such that \spad{p(x)} is \spadfun{true}
    ++ if \spad{number} is positive, all of them if
    ++ \spad{number} equals zero, and all but at most \spad{-number} if
    ++ \spad{number} is negative.
  remove_!: (S,%,Integer) -> %
    ++ remove!(x,ms,number) removes destructively at most \spad{number}
    ++ copies of element x if \spad{number} is positive, all
    ++ of them if \spad{number} equals zero, and all but at most
    ++ \spad{-number} if \spad{number} is negative.
  remove_!: ( S -> Boolean ,%,Integer) -> %
    ++ remove!(p,ms,number) removes destructively at most \spad{number}
    ++ copies of elements x such that \spad{p(x)} is
    ++ \spadfun{true} if \spad{number} is positive, all of them if
    ++ \spad{number} equals zero, and all but at most \spad{-number} if
    ++ \spad{number} is negative.

=====
MultivariatePolynomial examples
=====

The domain constructor `MultivariatePolynomial` is similar to `Polynomial` except that it specifies the variables to be used. `Polynomial` are available for `MultivariatePolynomial`. The abbreviation for `MultivariatePolynomial` is `MPOLY`. The type expressions

```

MultivariatePolynomial([x,y],Integer)
MPOLY([x,y],INT)

```

refer to the domain of multivariate polynomials in the variables `x` and `y` where the coefficients are restricted to be integers. The first variable specified is the main variable and the display of the polynomial reflects this.

This polynomial appears with terms in descending powers of the variable `x`.

```

m : MPOLY([x,y],INT) := (x^2 - x*y^3 +3*y)^2
      4      3 3      6      2      4      2
      x  - 2y x  + (y  + 6y)x  - 6y x + 9y
      Type: MultivariatePolynomial([x,y],Integer)

```

It is easy to see a different variable ordering by doing a conversion.

```

m :: MPOLY([y,x],INT)
      2 6      4      3 3      2      2      4
      x y  - 6x y  - 2x y  + 9y  + 6x y + x

```

Type: MultivariatePolynomial([y,x],Integer)

You can use other, unspecified variables, by using Polynomial in the coefficient type of MPOLY.

```
p : MPOLY([x,y],POLY INT)
      Type: Void
```

Conversions can be used to re-express such polynomials in terms of the other variables. For example, you can first push all the variables into a polynomial with integer coefficients.

```
p :: POLY INT
p
      Type: Polynomial Integer
```

Now pull out the variables of interest.

```
% :: MPOLY([a,b],POLY INT)
p
      Type: MultivariatePolynomial([a,b],Polynomial Integer)
```

Restriction:

Axiom does not allow you to create types where MultivariatePolynomial is contained in the coefficient type of Polynomial. Therefore, MPOLY([x,y],POLY INT) is legal but POLY MPOLY([x,y],INT) is not.

Multivariate polynomials may be combined with univariate polynomials to create types with special structures.

```
q : UP(x, FRAC MPOLY([y,z],INT))
      Type: Void
```

This is a polynomial in x whose coefficients are quotients of polynomials in y and z.

```
q := (x^2 - x*(z+1)/y + 2)^2
      2      2
      4      - 2z - 2 3      4y + z + 2z + 1 2      - 4z - 4
(7) x + ----- x + ----- x + ----- x + 4
      y          2          y
```

Type: UnivariatePolynomial(x,Fraction MultivariatePolynomial([y,z],Integer))

Use conversions for structural rearrangements. z does not appear in a denominator and so it can be made the main variable.

```
q :: UP(z, FRAC MPOLY([x,y],INT))
      2      3      2      2 4      3      2      2      2
x  2  - 2y x + 2x - 4y x      y x - 2y x + (4y + 1)x - 4y x + 4y
```

```

-- z + ----- z + -----
  2          2          2
 y          y          y
Type: UnivariatePolynomial(z,Fraction MultivariatePolynomial([x,y],Integer))

```

Or you can make a multivariate polynomial in x and z whose coefficients are fractions in polynomials in y.

```

q :: MPOLY([x,z], FRAC UP(y,INT))
  4      2      2 3      1 2      2      4y + 1 2      4      4
  x + (- - z - -)x + (-- z + -- z + -----)x + (- - z - -)x + 4
      y      y          2      2          2          y      y
Type: MultivariatePolynomial([x,z],Fraction UnivariatePolynomial(y,Integer))

```

A conversion like q :: MPOLY([x,y], FRAC UP(z,INT)) is not possible in this example because y appears in the denominator of a fraction. As you can see, Axiom provides extraordinary flexibility in the manipulation and display of expressions via its conversion facility.

— domain MPOLY MultivariatePolynomial —

```
)abbrev domain MPOLY MultivariatePolynomial
++ Author: Dave Barton, Barry Trager
++ Description:
++ This type is the basic representation of sparse recursive multivariate
++ polynomials whose variables are from a user specified list of symbols.
++ The ordering is specified by the position of the variable in the list.
++ The coefficient ring may be non commutative,
++ but the variables are assumed to commute.
```

```
MultivariatePolynomial(vl:List Symbol, R:Ring)
  == SparseMultivariatePolynomial(--SparseUnivariatePolynomial,

domain NSMP NewSparseMultivariatePolynomial

Based on the **PseudoRemainderSequence** package, the domain constructor **NewSparseMultivariatePolynomial** extends the constructor **SparseMultivariatePolynomial**. It also provides some additional operations related to polynomial system solving by means of triangular sets.

=====
 None examples
 =====

The None domain is not very useful for interactive work but it is provided nevertheless for completeness of the Axiom type system.

Probably the only place you will ever see it is if you enter an empty list with no type information.

```

[ ]
[]
                                     Type: List None

```

Such an empty list can be converted into an empty list of any other type.

```

[ ] :: List Float
[]
                                     Type: List Float

```

If you wish to produce an empty list of a particular type directly, such as List NonNegativeInteger, do it this way.

```
[ ]$List(NonNegativeInteger)
[]
```

Type: List NonNegativeInteger

=====
NottinghamGroup examples
=====

```

If F is a finite field with p^n elements, then we may form the group of all formal power series $\{t(1+a_1t+a_2t^2+\dots)\}$ where $u(0)=0$ and $u(0)=1$ and a_i is an element of F .

The group operation is substitution (composition). This is called the Nottingham Group.

The Nottingham Group is the projective limit of finite p -groups. Every finite p -group can be embedded in the Nottingham Group.

Chapter 16

Chapter O

domain OCT Octonion

The octonions have the following multiplication table:

1	i	j	k	E	I	J	K
i	-1	k	$-j$	I	$-E$	$-K$	J
j	$-k$	-1	i	J	K	$-E$	$-I$
k	j	$-i$	-1	K	$-J$	I	$-E$
E	$-I$	$-J$	$-K$	-1	i	j	k
I	E	$-K$	J	$-i$	-1	$-k$	j
J	K	E	$-I$	$-j$	k	-1	$-i$
K	$-J$	I	E	$-k$	$-j$	i	-1

There are 3 different kinds of associativity. An algebra is

- **power-associative** if the subalgebra generated by any one element is associative. That is, given any element e then $e * (e * e) = (e * e) * e$.
- **alternative** if the subalgebra generated by any two elements is associative. That is, given any two elements, a and b then $a * (a * b) = (a * a) * b$ and $a * (b * a) = (a * b) * a$ and $b * (a * a) = (b * a) * a$.
- **associative** if the subalgebra generated by any three elements is associative. That is, given any three elements a , b , and c then $a * (b * c) = (a * b) * c$.

The Octonions are power-associative and alternative but not associative, since $I * (J * K) \neq (I * J) * K$.

=====
Octonion examples
=====

The Octonions, also called the Cayley-Dixon algebra, defined over a commutative ring are an eight-dimensional non-associative algebra. Their construction from quaternions is similar to the construction of quaternions from complex numbers.

As Octonion creates an eight-dimensional algebra, you have to give eight components to construct an octonion.

```

oci1 := octon(1,2,3,4,5,6,7,8)
      1 + 2i + 3j + 4k + 5E + 6I + 7J + 8K
                        Type: Octonion Integer

```

```

oci2 := octon(7,2,3,-4,5,6,-7,0)
      7 + 2i + 3j - 4k + 5E + 6I - 7J
                        Type: Octonion Integer

```

Or you can use two quaternions to create an octonion.

```

oci3 := octon(quatern(-7,-12,3,-10), quatern(5,6,9,0))

```

```
- 7 - 12i + 3j - 10k + 5E + 6I + 9J
Type: Octonion Integer
```

You can easily demonstrate the non-associativity of multiplication.

```
(oci1 * oci2) * oci3 - oci1 * (oci2 * oci3)
2696i - 2928j - 4072k + 16E - 1192I + 832J + 2616K
Type: Octonion Integer
```

As with the quaternions, we have a real part, the imaginary parts i, j, k , and four additional imaginary parts E, I, J and K . These parts correspond to the canonical basis $(1, i, j, k, E, I, J, K)$.

For each basis element there is a component operation to extract the coefficient of the basis element for a given octonion.

```
[real oci1, imagi oci1, imagj oci1, imagk oci1, _
 imagE oci1, imagI oci1, imagJ oci1, imagK oci1]
[1,2,3,4,5,6,7,8]
Type: List PositiveInteger
```

A basis with respect to the quaternions is given by $(1, E)$. However, you might ask, what then are the commuting rules? To answer this, we create some generic elements.

We do this in Axiom by simply changing the ground ring from Integer to Polynomial Integer.

```
q : Quaternion Polynomial Integer := quatern(q1, qi, qj, qk)
q1 + qi i + qj j + qk k
Type: Quaternion Polynomial Integer
```

```
E : Octonion Polynomial Integer:= octon(0,0,0,0,1,0,0,0)
E
Type: Octonion Polynomial Integer
```

Note that quaternions are automatically converted to octonions in the obvious way.

```
q * E
q1 E + qi I + qj J + qk K
Type: Octonion Polynomial Integer
```

```
E * q
q1 E - qi I - qj J - qk K
Type: Octonion Polynomial Integer
```

```
q * 1$(Octonion Polynomial Integer)
q1 + qi i + qj j + qk k
Type: Octonion Polynomial Integer
```

```

1$(Octonion Polynomial Integer) * q
q1 + qi i + qj j + qk k
Type: Octonion Polynomial Integer

```

Finally, we check that the norm, defined as the sum of the squares of the coefficients, is a multiplicative map.

```

o : Octonion Polynomial Integer := octon(o1, oi, oj, ok, oE, oI, oJ, oK)
o1 + oi i + oj j + ok k + oE E + oI I + oJ J + oK K
Type: Octonion Polynomial Integer

```

```

norm o
  2      2      2      2      2      2      2      2
ok  + oj  + oi  + oK  + oJ  + oI  + oE  + o1
Type: Polynomial Integer

```

```

p : Octonion Polynomial Integer := octon(p1, pi, pj, pk, pE, pI, pJ, pK)
p1 + pi i + pj j + pk k + pE E + pI I + pJ J + pK K
Type: Octonion Polynomial Integer

```

Since the result is 0, the norm is multiplicative.

```

norm(o*p)-norm(p)*norm(o)
0
Type: Polynomial Integer

```

=====
OneDimensionalArray examples
=====

```

The OneDimensionalArray domain is used for storing data in a one-dimensional indexed data structure. Such an array is a homogeneous data structure in that all the entries of the array must belong to the same Axiom domain. Each array has a fixed length specified by the user and arrays are not extensible. The indexing of one-dimensional arrays is one-based. This means that the "first" element of an array is given the index 1.

To create a one-dimensional array, apply the operation oneDimensionalArray to a list.

```

oneDimensionalArray [i**2 for i in 1..10]

```

```
[1,4,9,16,25,36,49,64,81,100]
Type: OneDimensionalArray PositiveInteger
```

Another approach is to first create `a`, a one-dimensional array of 10 0's. `OneDimensionalArray` has the convenient abbreviation `ARRAY1`.

```
a : ARRAY1 INT := new(10,0)
[0,0,0,0,0,0,0,0,0,0]
Type: OneDimensionalArray Integer
```

Set each i -th element to i , then display the result.

```
for i in 1..10 repeat a.i := i; a
[1,2,3,4,5,6,7,8,9,10]
Type: OneDimensionalArray Integer
```

Square each element by mapping the function $i \mapsto i^2$ onto each element.

```
map!(i +-> i ** 2,a); a
[1,4,9,16,25,36,49,64,81,100]
Type: OneDimensionalArray Integer
```

Reverse the elements in place.

```
reverse! a
[100,81,64,49,36,25,16,9,4,1]
Type: OneDimensionalArray Integer
```

Swap the 4th and 5th element.

```
swap!(a,4,5); a
[100,81,64,36,49,25,16,9,4,1]
Type: OneDimensionalArray Integer
```

Sort the elements in place.

```
sort! a
[1,4,9,16,25,36,49,64,81,100]
Type: OneDimensionalArray Integer
```

Create a new one-dimensional array `b` containing the last 5 elements of `a`.

```
b := a(6..10)
[36,49,64,81,100]
Type: OneDimensionalArray Integer
```

Replace the first 5 elements of `a` with those of `b`.

```
copyInto!(a,b,1)
[36,49,64,81,100,36,49,64,81,100]
```

Type: OneDimensionalArray Integer

)abbrev domain OMDEV OpenMathDevice
++ Author: Vilya Harvey
++ Description:
++ \spadtype{OpenMathDevice} provides support for reading
++ and writing openMath objects to files, strings etc. It also provides
++ access to low-level operations from within the interpreter.

OpenMathDevice(): with
  OMopenFile : (String, String, OpenMathEncoding) -> %
  ++ OMopenFile(f,mode,enc) opens file \axiom{f} for reading or writing
  ++ OpenMath objects (depending on \axiom{mode} which can be "r", "w"
  ++ or "a" for read, write and append respectively), in the encoding
  ++ \axiom{enc}.
  OMopenString : (String, OpenMathEncoding) -> %
  ++ OMopenString(s,mode) opens the string \axiom{s} for reading or writing
  ++ OpenMath objects in encoding \axiom{enc}.
  OMclose : % -> Void
  ++ OMclose(dev) closes \axiom{dev}, flushing output if necessary.
  OMsetEncoding : (% , OpenMathEncoding) -> Void
  ++ OMsetEncoding(dev,enc) sets the encoding used for reading or writing
  ++ OpenMath objects to or from \axiom{dev} to \axiom{enc}.
  OMputApp : % -> Void
  ++ OMputApp(dev) writes a begin application token to \axiom{dev}.
  OMputAtp : % -> Void
  ++ OMputAtp(dev) writes a begin attribute pair token to \axiom{dev}.
  OMputAttr : % -> Void
  ++ OMputAttr(dev) writes a begin attribute token to \axiom{dev}.
  OMputBind : % -> Void
  ++ OMputBind(dev) writes a begin binder token to \axiom{dev}.
  OMputBVar : % -> Void
  ++ OMputBVar(dev) writes a begin bound variable list token to \axiom{dev}.
  OMputError : % -> Void
  ++ OMputError(dev) writes a begin error token to \axiom{dev}.
  OMputObject : % -> Void
  ++ OMputObject(dev) writes a begin object token to \axiom{dev}.
  OMputEndApp : % -> Void
  ++ OMputEndApp(dev) writes an end application token to \axiom{dev}.
  OMputEndAtp : % -> Void
  ++ OMputEndAtp(dev) writes an end attribute pair token to \axiom{dev}.
  OMputEndAttr : % -> Void
  ++ OMputEndAttr(dev) writes an end attribute token to \axiom{dev}.
  OMputEndBind : % -> Void
  ++ OMputEndBind(dev) writes an end binder token to \axiom{dev}.
  OMputEndBVar : % -> Void
  ++ OMputEndBVar(dev) writes an end bound variable list token to \axiom{dev}.
  OMputEndError : % -> Void
  ++ OMputEndError(dev) writes an end error token to \axiom{dev}.

```

```

OMputEndObject: % -> Void
++ OMputEndObject(dev) writes an end object token to \axiom{dev}.
OMputInteger : (% , Integer) -> Void
++ OMputInteger(dev,i) writes the integer \axiom{i} to \axiom{dev}.
OMputFloat : (% , DoubleFloat) -> Void
++ OMputFloat(dev,i) writes the float \axiom{i} to \axiom{dev}.
OMputVariable : (% , Symbol) -> Void
++ OMputVariable(dev,i) writes the variable \axiom{i} to \axiom{dev}.
OMputString : (% , String) -> Void
++ OMputString(dev,i) writes the string \axiom{i} to \axiom{dev}.
OMputSymbol : (% , String, String) -> Void
++ OMputSymbol(dev,cd,s) writes the symbol \axiom{s} from CD \axiom{cd}
++ to \axiom{dev}.

OMgetApp : % -> Void
++ OMgetApp(dev) reads a begin application token from \axiom{dev}.
OMgetAtp : % -> Void
++ OMgetAtp(dev) reads a begin attribute pair token from \axiom{dev}.
OMgetAttr : % -> Void
++ OMgetAttr(dev) reads a begin attribute token from \axiom{dev}.
OMgetBind : % -> Void
++ OMgetBind(dev) reads a begin binder token from \axiom{dev}.

++ Description:
++ \spadtype{OpenMathErrorKind} represents different kinds
++ of OpenMath errors: specifically parse errors, unknown CD or symbol
++ errors, and read errors.

OpenMathErrorKind() : SetCategory with
  coerce          : Symbol -> %
  ++ coerce(u) creates an OpenMath error object of an appropriate type if
  ++ \axiom{u} is one of \axiom{OMParseError}, \axiom{OMReadError},
  ++ \axiom{OMUnknownCD} or \axiom{OMUnknownSymbol}, otherwise it
  ++ raises a runtime error.
  OMParseError?   : % -> Boolean
  ++ OMParseError?(u) tests whether u is an OpenMath parsing error.
  OMUnknownCD?    : % -> Boolean
  ++ OMUnknownCD?(u) tests whether u is an OpenMath unknown CD error.
  OMUnknownSymbol? : % -> Boolean
  ++ OMUnknownSymbol?(u) tests whether u is an OpenMath unknown symbol error.
  OMReadError?    : % -> Boolean
  ++ OMReadError?(u) tests whether u is an OpenMath read error.
== add
Rep := Union(parseError:"OMParseError", unknownCD:"OMUnknownCD",
             unknownSymbol:"OMUnknownSymbol", readError:"OMReadError")

OMParseError?(u) == (u case parseError)$Rep
OMUnknownCD?(u) == (u case unknownCD)$Rep
OMUnknownSymbol?(u) == (u case unknownSymbol)$Rep
OMReadError?(u) == (u case readError)$Rep

coerce(s:Symbol):% ==
  s = OMParseError    => ["OMParseError"]$Rep
  s = OMUnknownCD     => ["OMUnknownCD"]$Rep
  s = OMUnknownSymbol => ["OMUnknownSymbol"]$Rep
  s = OMReadError     => ["OMReadError"]$Rep
  error concat(string s, " is not a valid OpenMathErrorKind.")

a = b == (a=b)$Rep

coerce(e:%):OutputForm == coerce(e)$Rep

=====
Operator examples
=====
```

Given any ring R , the ring of the Integer-linear operators over R is called `Operator(R)`. To create an operator over R , first create a basic operator using the operation operator, and then convert it to `Operator(R)` for the R you want.

We choose R to be the two by two matrices over the integers.

```
R := SQMATRIX(2, INT)
   SquareMatrix(2,Integer)
                                Type: Domain
```

Create the operator `tilde` on R .

```
t := operator("tilde") :: OP(R)
   tilde
                                Type: Operator SquareMatrix(2,Integer)
```

Since `Operator` is unexposed we must either package-call operations from it, or expose it explicitly. For convenience we will do the latter.

Expose `Operator`.

```
)set expose add constructor Operator
```

To attach an evaluation function (from R to R) to an operator over R , use `evaluate(op, f)` where `op` is an operator over R and `f` is a function $R \rightarrow R$. This needs to be done only once when the operator is defined. Note that `f` must be Integer-linear (that is, $f(ax+y) = a f(x) + f(y)$ for any integer a , and any x and y in R).

We now attach the transpose map to the above operator `t`.

```
evaluate(t, m +-> transpose m)
   tilde
                                Type: Operator SquareMatrix(2,Integer)
```

Operators can be manipulated formally as in any ring: + is the pointwise addition and * is composition. Any element x of R can be converted to an operator op(x) over R, and the evaluation function of op(x) is left-multiplication by x.

Multiplying on the left by this matrix swaps the two rows.

```
s : R := matrix [ [0, 1], [1, 0] ]
      +0 1+
      |   |
      +1 0+
                                     Type: SquareMatrix(2,Integer)
```

Can you guess what is the action of the following operator?

```
rho := t * s
      +0 1+
      tilde|   |
      +1 0+
                                     Type: Operator SquareMatrix(2,Integer)
```

Hint: applying rho four times gives the identity, so rho^4-1 should return 0 when applied to any two by two matrix.

```
z := rho**4 - 1
      +0 1+   +0 1+   +0 1+   +0 1+
      - 1 + tilde|   |tilde|   |tilde|   |tilde|   |
      +1 0+   +1 0+   +1 0+   +1 0+
                                     Type: Operator SquareMatrix(2,Integer)
```

Now check with this matrix.

```
m:R := matrix [ [1, 2], [3, 4] ]
      +1 2+
      |   |
      +3 4+
                                     Type: SquareMatrix(2,Integer)
```

```
z m
      +0 0+
      |   |
      +0 0+
                                     Type: SquareMatrix(2,Integer)
```

As you have probably guessed by now, rho acts on matrices by rotating the elements clockwise.

```
rho m
      +3 1+
      |   |
```

```

+4 2+
                                     Type: SquareMatrix(2,Integer)

rho rho m
+4 3+
|   |
+2 1+
                                     Type: SquareMatrix(2,Integer)

(rho^3) m
+2 4+
|   |
+1 3+
                                     Type: SquareMatrix(2,Integer)

```

Do the swapping of rows and transposition commute? We can check by computing their bracket.

```

b := t * s - s * t
+0 1+           +0 1+
- | |tilde + tilde| |
+1 0+           +1 0+
                                     Type: Operator SquareMatrix(2,Integer)

```

Now apply it to m.

```

b m
+1 - 3+
|   |
+3 - 1+
                                     Type: SquareMatrix(2,Integer)

```

Next we demonstrate how to define a differential operator on a polynomial ring.

This is the recursive definition of the n-th Legendre polynomial.

```

L n ==
n = 0 => 1
n = 1 => x
(2*n-1)/n * x * L(n-1) - (n-1)/n * L(n-2)
                                     Type: Void

```

Create the differential operator d/dx on polynomials in x over the rational numbers.

```

dx := operator("D") :: OP(POLY FRAC INT)
D
                                     Type: Operator Polynomial Fraction Integer

```

Now attach the map to it.

```
evaluate(dx, p +-> D(p, 'x'))
D
Type: Operator Polynomial Fraction Integer
```

This is the differential equation satisfied by the n-th Legendre polynomial.

```
E n == (1 - x**2) * dx**2 - 2 * x * dx + n*(n+1)
Type: Void
```

Now we verify this for n = 15. Here is the polynomial.

```
L 15
 9694845 15 35102025 13 50702925 11 37182145 9 14549535 7
----- x - ----- x + ----- x - ----- x + ----- x
 2048      2048      2048      2048      2048
+
 2909907 5 255255 3 6435
----- x + ----- x - ----- x
 2048      2048      2048
Type: Polynomial Fraction Integer
```

Here is the operator.

```
E 15
240 - 2x D - (x - 1)D
Type: Operator Polynomial Fraction Integer
```

Here is the evaluation.

```
(E 15)(L 15)
0
Type: Polynomial Fraction Integer
```

```

This type represents the finite direct or cartesian product of an underlying ordered component type. The ordering on the type is determined by its third argument which represents the less than function on vectors. This type is a suitable third argument for `GeneralDistributedMultivariatePolynomial`.

=====
OrderedFreeMonoid examples
=====

```

The free monoid on a set S is the monoid of finite products of the form $\text{reduce}(*,[s_i ** n_i])$ where the s_i 's are in S , and the n_i 's are non-negative integers. The multiplication is not commutative. For two elements x and y the relation $x < y$ holds if either $\text{length}(x) < \text{length}(y)$ holds or if these lengths are equal and if x is smaller than y w.r.t. the lexicographical ordering induced by S . This domain inherits implementation from `FreeMonoid`.

```
m1:=(x*y*y*z)$OFMONOID(Symbol)
```

```
m2:=(x*y)$OFMONOID(Symbol)
```

```
lquo(m1,m2)
```

```
m3:=(y*y)$OFMONOID(Symbol)
```

```
div(m1,m2)
```

```
div(m1,m3)
```

```
m4:=(y^3)$OFMONOID(Symbol)
```

```
div(m1,m4)
```

Build the non-commutative algebra $h=k[x,y]$ and then make computations in h using some predefined rules for x and y . For example, giving

```

x*y*x=y*x*y
x*x=a*x+b

```

$$y*y = a*y + b$$

where a and b are generic elements of k .

Then reduce the polynomials in x and y according to the previous rules. That is, given

$$(x+y)^2 \quad (= x^2 + x*y + y*x + y^2)$$

should reduce to

$$a*(x+y) + 2*b + x*y + y*x$$

We can reduce the clutter of the work by defining macros for the types of the domains we need to create. So first we create those macros.

We create generic elements of k . First we define a macro for the domain of ordered variables (OVAR is OrderedVariableList)

$$C \Rightarrow \text{OVAR } [a,b]$$

Next we define a macro for the commutative field domain $k = Q[a,b]$ where Q is Fraction(Integer) and SMP is SparseMultivariatePolynomials

$$K \Rightarrow \text{SMP}(\text{FRAC INT}, C)$$

Now we need some non-commutative variables so we create a macro for that.

$$V \Rightarrow \text{OVAR } [x,y]$$

And now we need to define the non-commutative algebra $k = k[x,y]$.

We use the domain XDistributedPolynomial (XDPOLY) as a macro.

$$H \Rightarrow \text{XDPOLY}(V, K)$$

The non-commutative variables are in an Ordered Free Monoid

$$M \Rightarrow \text{OFMONOID } V$$

We have three rules to apply. So we create a function that examines one term. Substitution rules are applied to words from the monoid over the variables and return polynomials. If any rule matches we construct the substitution, create a new monomial term and return it.

```
subs(w:M):H ==
-- x*y*x = y*x*y
n1:=lquo(w, (x::V*y::V*x::V)$M)$M
n1 case "failed" => monom(w,1)$H
-- x*x = a*x+b
n2:=lquo(w, (x::V^2)$M)$M
```

```

n2 case "failed" => monom(w,1)$H
-- y*y = a*y+b
n3:lquo(w,(y::V^2)$M)$M
n3 case "failed" => monom(w,1)$H
  monom(n3,1)$H * (a::K*y::V+b::K)$M * monom(n3,1)$H
  monom(n2,1)$H * (a::K*x::V+b::K)$H * monom(n2,1)$H
  monom(n1,1)$H * (y::V*x::V*y::V)$H * monom(n1,1)$H

```

We apply these rules to a term, remembering the coefficient

```

newterm(x:Record(k:M,c:K)):H == x.c*subs(x,k)

```

And now we create a function to reconstruct the polynomial term by term.

```

newpoly(t:H):H == reduce(+,map(newterm,listOfTerms(t)))

```

For example,

```

p1:(x::V+y::V)$H^2
newpoly(p1)
p2:=(x::V+y::V)$H^3
pNew:=newpoly(p2)

```

But the rules should be applied more than once so we create a function to iterate the rules until nothing changes.

```

reduce(p:H):H ==
  p2 := newpoly(p)
  p3 := newpoly(p2)
  while p3 ~= p2 repeat
    p2 := p3
    p3 := newpoly(p2)
  p3

```

And we can see it work

```

reduce(p2)

```

=====
OrderedVariableList examples
=====
```

The domain `OrderedVariableList` provides symbols which are restricted to a particular list and have a definite ordering. Those two features are specified by a `List Symbol` object that is the argument to the domain.

This is a sample ordering of three symbols.

```
ls:List Symbol:=['x','a','z']
  [x,a,z]
                                     Type: List Symbol
```

Let's build the domain

```
Z:=OVAR ls
  OrderedVariableList [x,a,z]
                                     Type: Domain
```

How many variables does it have?

```
size()$Z
  3
                                     Type: NonNegativeInteger
```

They are (in the imposed order)

```
lv:=[index(i::PI)$Z for i in 1..size()$Z]
  [x,a,z]
                                     Type: List OrderedVariableList [x,a,z]
```

Check that the ordering is right

```
sorted?(>,lv)
  true
                                     Type: Boolean
```

=====
OrderlyDifferentialPolynomial examples
=====

```

Many systems of differential equations may be transformed to equivalent systems of ordinary differential equations where the equations are expressed polynomially in terms of the unknown functions. In Axiom, the domain constructors `OrderlyDifferentialPolynomial` (abbreviated `ODPOL`) and `SequentialDifferentialPolynomial` (abbreviation `SDPOL`) implement two domains of ordinary differential polynomials over any differential ring. In the simplest case, this differential ring is usually either the ring of integers, or the field of rational numbers. However, Axiom can handle ordinary differential polynomials over a field of rational functions in a single indeterminate.

The two domains ODPOL and SDPOL are almost identical, the only difference being the choice of a different ranking, which is an ordering of the derivatives of the indeterminates. The first domain uses an orderly ranking, that is, derivatives of higher order are ranked higher, and derivatives of the same order are ranked alphabetically. The second domain uses a sequential ranking, where derivatives are ordered first alphabetically by the differential indeterminates, and then by order. A more general domain constructor, `DifferentialSparseMultivariatePolynomial` (abbreviation DSMP) allows both a user-provided list of differential indeterminates as well as a user-defined ranking. We shall illustrate `ODPOL(FRAC INT)`, which constructs a domain of ordinary differential polynomials in an arbitrary number of differential indeterminates with rational numbers as coefficients.

```
dpol:= ODPOL(FRAC INT)
      OrderlyDifferentialPolynomial Fraction Integer
                        Type: Domain
```

A differential indeterminate w may be viewed as an infinite sequence of algebraic indeterminates, which are the derivatives of w . To facilitate referencing these, Axiom provides the operation `makeVariable` to convert an element of type `Symbol` to a map from the natural numbers to the differential polynomial ring.

```
w := makeVariable('w)$dpol
     theMap(DPOLCAT-;makeVariable;AM;17!0,0)
Type: (NonNegativeInteger -> OrderlyDifferentialPolynomial Fraction Integer)
```

```
z := makeVariable('z)$dpol
     theMap(DPOLCAT-;makeVariable;AM;17!0,0)
Type: (NonNegativeInteger -> OrderlyDifferentialPolynomial Fraction Integer)
```

The fifth derivative of w can be obtained by applying the map w to the number 5. Note that the order of differentiation is given as a subscript (except when the order is 0).

```
w.5
  w
  5
                        Type: OrderlyDifferentialPolynomial Fraction Integer
```

```
w 0
  w
                        Type: OrderlyDifferentialPolynomial Fraction Integer
```

The first five derivatives of z can be generated by a list.

```
[z.i for i in 1..5]
[z ,z ,z ,z ,z ]
```

$$1 \ 2 \ 3 \ 4 \ 5$$

Type: List OrderlyDifferentialPolynomial Fraction Integer

The usual arithmetic can be used to form a differential polynomial from the derivatives.

$$f := w \cdot 4 - w \cdot 1 \cdot w \cdot 1 \cdot z \cdot 3$$

$$\frac{w^2 - w^2 z}{4 \cdot 1 \cdot 3}$$

Type: OrderlyDifferentialPolynomial Fraction Integer

$$g := (z \cdot 1)^3 \cdot (z \cdot 2)^2 - w \cdot 2$$

$$\frac{z^3 z^2 - w}{1 \cdot 2 \cdot 2}$$

Type: OrderlyDifferentialPolynomial Fraction Integer

The operation D computes the derivative of any differential polynomial.

D(f)

$$\frac{w^2 - w^2 z - 2w w z}{5 \cdot 1 \cdot 4 \cdot 1 \cdot 2 \cdot 3}$$

Type: OrderlyDifferentialPolynomial Fraction Integer

The same operation can compute higher derivatives, like the fourth derivative.

D(f,4)

$$\frac{w^2 - w^2 z - 8w w z + (-12w w - 12w^2)z - 2w z w}{8 \cdot 1 \cdot 7 \cdot 1 \cdot 2 \cdot 6 \cdot 1 \cdot 3 \cdot 2 \cdot 5 \cdot 1 \cdot 3 \cdot 5} + \frac{(-8w w - 24w w)z - 8w z w - 6w^2 z}{1 \cdot 4 \cdot 2 \cdot 3 \cdot 4 \cdot 2 \cdot 3 \cdot 4 \cdot 3 \cdot 3}$$

Type: OrderlyDifferentialPolynomial Fraction Integer

The operation makeVariable creates a map to facilitate referencing the derivatives of f, similar to the map w.

$$df := \text{makeVariable}(f)\$dpol$$

$$\text{theMap}(\text{DPOLCAT-}; \text{makeVariable}; \text{AM}; 17!0, 0)$$

Type: (NonNegativeInteger -> OrderlyDifferentialPolynomial Fraction Integer)

The fourth derivative of f may be referenced easily.

df.4

$$w^2 - w^2 z - 8w w z + (-12w w - 12w^2)z - 2w z w$$

$$\begin{array}{ccccccc}
 8 & 1 & 7 & 1 & 2 & 6 & 1 & 3 & 2 & 5 & 1 & 3 & 5 \\
 + & & & & & & & & & & & & \\
 & & & & & & & & & & & & 2 \\
 (- & 8w & w & - & 24w & w &)z & - & 8w & z & w & - & 6w & z \\
 & 1 & 4 & & 2 & 3 & 4 & & 2 & 3 & 4 & & 3 & 3 \\
 & & & & & & & & & & & & & \\
 & & & & & & & & & & & & & \text{Type: OrderlyDifferentialPolynomial Fraction Integer}
 \end{array}$$

The operation order returns the order of a differential polynomial, or the order in a specified differential indeterminate.

```
order(g)
2
Type: PositiveInteger
```

```
order(g, 'w)
2
Type: PositiveInteger
```

The operation differentialVariables returns a list of differential indeterminates occurring in a differential polynomial.

```
differentialVariables(g)
[z,w]
Type: List Symbol
```

The operation degree returns the degree, or the degree in the differential indeterminate specified.

```
degree(g)
2 3
z z
2 1
Type: IndexedExponents OrderlyDifferentialVariable Symbol
```

```
degree(g, 'w)
1
Type: PositiveInteger
```

The operation weights returns a list of weights of differential monomials appearing in differential polynomial, or a list of weights in a specified differential indeterminate.

```
weights(g)
[7,2]
Type: List NonNegativeInteger
```

```
weights(g,'w)
[2]
Type: List NonNegativeInteger
```

The operation `weight` returns the maximum weight of all differential monomials appearing in the differential polynomial.

```
weight(g)
7
Type: PositiveInteger
```

A differential polynomial is isobaric if the weights of all differential monomials appearing in it are equal.

```
isobaric?(g)
false
Type: Boolean
```

To substitute differentially, use `eval`. Note that we must coerce `w` to `Symbol`, since in `ODPOL`, differential indeterminates belong to the domain `Symbol`. Compare this result to the next, which substitutes algebraically (no substitution is done since `w.0` does not appear in `g`).

```
eval(g,[w::Symbol],[f])
      2          2          3 2
- w + w z + 4w w z + (2w w + 2w )z + z z
  6  1 5    1 2 4    1 3    2 3    1 2
Type: OrderlyDifferentialPolynomial Fraction Integer
```

```
eval(g,variables(w.0),[f])
  3 2
z z - w
  1 2  2
Type: OrderlyDifferentialPolynomial Fraction Integer
```

Since `OrderlyDifferentialPolynomial` belongs to `PolynomialCategory`, all the operations defined in the latter category, or in packages for the latter category, are available.

```
monomials(g)
  3 2
[z z , - w ]
  1 2    2
Type: List OrderlyDifferentialPolynomial Fraction Integer
```

```
variables(g)
[z ,w ,z ]
  2 2 1
Type: List OrderlyDifferentialVariable Symbol
```

```
gcd(f,g)
1
Type: OrderlyDifferentialPolynomial Fraction Integer
```

```

groebner([f,g])
      2      3 2
[w - w z ,z z - w ]
      4      1 3 1 2      2
Type: List OrderlyDifferentialPolynomial Fraction Integer

```

The next three operations are essential for elimination procedures in differential polynomial rings. The operation leader returns the leader of a differential polynomial, which is the highest ranked derivative of the differential indeterminates that occurs.

```

lg:=leader(g)
      z
      2
Type: OrderlyDifferentialVariable Symbol

```

The operation separant returns the separant of a differential polynomial, which is the partial derivative with respect to the leader.

```

sg:=separant(g)
      3
      2z z
      1 2
Type: OrderlyDifferentialPolynomial Fraction Integer

```

The operation initial returns the initial, which is the leading coefficient when the given differential polynomial is expressed as a polynomial in the leader.

```

ig:=initial(g)
      3
      z
      1
Type: OrderlyDifferentialPolynomial Fraction Integer

```

Using these three operations, it is possible to reduce f modulo the differential ideal generated by g. The general scheme is to first reduce the order, then reduce the degree in the leader. First, eliminate z.3 using the derivative of g.

```

g1 := D g
      3      2 3
      2z z z - w + 3z z
      1 2 3      3      1 2
Type: OrderlyDifferentialPolynomial Fraction Integer

```

Find its leader.

```

lg1:= leader g1
      z

```

3

Type: OrderlyDifferentialVariable Symbol

Differentiate f partially with respect to this leader.

```
pdf:=D(f, lg1)
      2
     - w
      1
```

Type: OrderlyDifferentialPolynomial Fraction Integer

Compute the partial remainder of f with respect to g.

```
prf:=sg * f- pdf * g1
      3      2      2 2 3
     2z z w - w w + 3w z z
      1 2 4      1 3      1 1 2
```

Type: OrderlyDifferentialPolynomial Fraction Integer

Note that high powers of lg still appear in prf. Compute the leading coefficient of prf as a polynomial in the leader of g.

```
lcf:=leadingCoefficient univariate(prf, lg)
      2 2
     3w z
      1 1
```

Type: OrderlyDifferentialPolynomial Fraction Integer

Finally, continue eliminating the high powers of lg appearing in prf to obtain the (pseudo) remainder of f modulo g and its derivatives.

```
ig * prf - lcf * g * lg
      6      2 3      2 2
     2z z w - w z w + 3w z w z
      1 2 4      1 1 3      1 1 2 2
```

Type: OrderlyDifferentialPolynomial Fraction Integer

=====
OrderlyDifferentialVariable examples
=====

```

OrderlyDifferentialVariable adds a commonly used orderly ranking to the set of derivatives of an ordered list of differential indeterminates. An orderly ranking is a ranking $<$ of the derivatives with the property that for two derivatives u and v , $u < v$ if the order of u is less than that of v .

This domain belongs to DifferentialVariableCategory. It defines weight to be just order, and it defines an orderly ranking $<$ on derivatives u via the lexicographic order on the pair $(\text{order}(u), \text{variable}(u))$.

```

)abbrev domain OUTFORM OutputForm
++ Author: SMW March/88
++ Description:
++ This domain is used to create and manipulate mathematical expressions
++ for output. It is intended to provide an insulating layer between
++ the expression rendering software (e.g.FORTRAN, TeX, or Script) and
  
```

++ the output coercions in the various domains.

```

OutputForm(): SetCategory with
--% Printing
print : $ -> Void
  ++ print(u) prints the form u.
message: String -> $
  ++ message(s) creates an form with no string quotes
  ++ from string s.
messagePrint: String -> Void
  ++ messagePrint(s) prints s without string quotes. Note:
  ++ \spad{messagePrint(s)} is equivalent to \spad{print message(s)}.
--% Creation of atomic forms
outputForm: Integer -> $
  ++ outputForm(n) creates an form for integer n.
outputForm: Symbol -> $
  ++ outputForm(s) creates an form for symbol s.
outputForm: String -> $
  ++ outputForm(s) creates an form for string s.
outputForm: DoubleFloat -> $
  ++ outputForm(sf) creates an form for small float sf.
empty : () -> $
  ++ empty() creates an empty form.

--% Sizings
width: $ -> Integer
  ++ width(f) returns the width of form f (an integer).
height: $ -> Integer
  ++ height(f) returns the height of form f (an integer).
width: -> Integer
  ++ width() returns the width of the display area (an integer).
height: -> Integer
  ++ height() returns the height of the display area (an integer).
subHeight: $ -> Integer
  ++ subHeight(f) returns the height of form f below the base line.
superHeight: $ -> Integer
  ++ superHeight(f) returns the height of form f above the base line.
--% Space manipulations
hspace: Integer -> $ ++ hspace(n) creates white space of width n.
vspace: Integer -> $ ++ vspace(n) creates white space of height n.
rspace: (Integer,Integer) -> $
  ++ rspace(n,m) creates rectangular white space, n wide by m high.
--% Area adjustments
left: ($,Integer) -> $
  ++ left(f,n) left-justifies form f within space of width n.
right: ($,Integer) -> $
  ++ right(f,n) right-justifies form f within space of width n.
center: ($,Integer) -> $
  ++ center(f,n) centers form f within space of width n.
left: $ -> $

```

```

++ left(f) left-justifies form f in total space.
right: $ -> $
++ right(f) right-justifies form f in total space.
center: $ -> $
++ center(f) centers form f in total space.

--% Area manipulations
hconcat: ($,$) -> $
++ hconcat(f,g) horizontally concatenate forms f and g.
vconcat: ($,$) -> $
++ vconcat(f,g) vertically concatenates forms f and g.
hconcat: List $ -> $
++ hconcat(u) horizontally concatenates all forms in list u.
vconcat: List $ -> $
++ vconcat(u) vertically concatenates all forms in list u.

--% Application formers
prefix: ($, List $) -> $
++ prefix(f,l) creates a form depicting the n-ary prefix
++ application of f to a tuple of arguments given by list l.
infix: ($, List $) -> $
++ infix(f,l) creates a form depicting the n-ary application
++ of infix operation f to a tuple of arguments l.
infix: ($, $, $) -> $
++ infix(op, a, b) creates a form which prints as: a op b.
postfix: ($, $) -> $
++ postfix(op, a) creates a form which prints as: a op.
infix?: $ -> Boolean
++ infix?(op) returns true if op is an infix operator,
++ and false otherwise.
elt: ($, List $) -> $
++ elt(op,l) creates a form for application of op
++ to list of arguments l.

--% Special forms
string: $ -> $
++ string(f) creates f with string quotes.
label: ($, $) -> $
++ label(n,f) gives form f an equation label n.
box: $ -> $
++ box(f) encloses f in a box.
matrix: List List $ -> $
++ matrix(llf) makes llf (a list of lists of forms) into
++ a form which displays as a matrix.
zag: ($, $) -> $
++ zag(f,g) creates a form for the continued fraction form for f over g.
root: $ -> $
++ root(f) creates a form for the square root of form f.
root: ($, $) -> $
++ root(f,n) creates a form for the nth root of form f.

```

```

over:    ($, $) -> $
++ over(f,g) creates a form for the vertical fraction of f over g.
slash:   ($, $) -> $
++ slash(f,g) creates a form for the horizontal fraction of f over g.
assign:  ($, $) -> $
++ assign(f,g) creates a form for the assignment \spad{f := g}.
rarrow:  ($, $) -> $
++ rarrow(f,g) creates a form for the mapping \spad{f -> g}.
differentiate: ($, NonNegativeInteger) -> $
++ differentiate(f,n) creates a form for the nth derivative of f,
++ e.g. \spad{f'}, \spad{f''}, \spad{f'''},
++ "f super \spad{iv}".
binomial: ($, $) -> $
++ binomial(n,m) creates a form for the binomial coefficient of n and m.

--% Scripts
sub:     ($, $) -> $
++ sub(f,n) creates a form for f subscripted by n.
super:   ($, $) -> $
++ super(f,n) creates a form for f superscripted by n.
presub:  ($, $) -> $
++ presub(f,n) creates a form for f presubscripted by n.
presuper:($, $) -> $
++ presuper(f,n) creates a form for f presuperscripted by n.
scripts: ($, List $) -> $
++ \spad{scripts}(f, [sub, super, presuper, presub])
++ creates a form for f with scripts on all 4 corners.
supersub:($, List $) -> $
++ supersub(a, [sub1,super1,sub2,super2,...])
++ creates a form with each subscript aligned
++ under each superscript.

--% Diacritical marks
quote:   $ -> $
++ quote(f) creates the form f with a prefix quote.
dot:     $ -> $
++ dot(f) creates the form with a one dot overhead.
dot:     ($, NonNegativeInteger) -> $
++ dot(f,n) creates the form f with n dots overhead.
prime:   $ -> $
++ prime(f) creates the form f followed by a suffix prime (single quote).
prime:   ($, NonNegativeInteger) -> $
++ prime(f,n) creates the form f followed by n primes.
overbar: $ -> $
++ overbar(f) creates the form f with an overbar.
overlabel: ($, $) -> $
++ overlabel(x,f) creates the form f with "x overbar" over the top.

--% Plexes
sum:     ($) -> $

```

```

++ sum(expr) creates the form prefixing expr by a capital sigma.
sum:    ($, $)  -> $
++ sum(expr,lowerlimit) creates the form prefixing expr by
++ a capital sigma with a lowerlimit.
sum:    ($, $, $) -> $
++ sum(expr,lowerlimit,upperlimit) creates the form prefixing expr by
++ a capital sigma with both a lowerlimit and upperlimit.
prod:   ($)    -> $
++ prod(expr) creates the form prefixing expr by a capital pi.
prod:   ($, $)  -> $
++ prod(expr,lowerlimit) creates the form prefixing expr by
++ a capital pi with a lowerlimit.
prod:   ($, $, $) -> $
++ prod(expr,lowerlimit,upperlimit) creates the form prefixing expr by
++ a capital pi with both a lowerlimit and upperlimit.
int:    ($)    -> $
++ int(expr) creates the form prefixing expr with an integral sign.
int:    ($, $)  -> $
++ int(expr,lowerlimit) creates the form prefixing expr by an
++ integral sign with a lowerlimit.
int:    ($, $, $) -> $
++ int(expr,lowerlimit,upperlimit) creates the form prefixing expr by
++ an integral sign with both a lowerlimit and upperlimit.

--% Matchfix forms
brace:  $ -> $
++ brace(f) creates the form enclosing f in braces (curly brackets).
brace:  List $ -> $
++ brace(lf) creates the form separating the elements of lf
++ by commas and encloses the result in curly brackets.
bracket: $ -> $
++ bracket(f) creates the form enclosing f in square brackets.
bracket: List $ -> $
++ bracket(lf) creates the form separating the elements of lf
++ by commas and encloses the result in square brackets.
paren:  $ -> $
++ paren(f) creates the form enclosing f in parentheses.
paren:  List $ -> $
++ paren(lf) creates the form separating the elements of lf
++ by commas and encloses the result in parentheses.

--% Separators for aggregates
pile:   List $ -> $
++ pile(l) creates the form consisting of the elements of l which
++ displays as a pile, i.e. the elements begin on a new line and
++ are indented right to the same margin.

commaSeparate: List $ -> $
++ commaSeparate(l) creates the form separating the elements of l
++ by commas.

```

```

semicolonSeparate: List $ -> $
  ++ semicolonSeparate(l) creates the form separating the elements of l
  ++ by semicolons.

— domain PADICRC PAdicRationalConstructor —

```
)abbrev domain PADICRC PAdicRationalConstructor
++ Author: Clifton J. Williamson
++ Date Created: 10 May 1990
++ Date Last Updated: 10 May 1990
++ Description:
++ This is the category of stream-based representations of Qp.

PAdicRationalConstructor(p,PADIC): Exports == Implementation where
  p      : Integer
  PADIC  : PAdicIntegerCategory p
  CF     ==> ContinuedFraction
  I      ==> Integer
  NNI    ==> NonNegativeInteger
  OUT    ==> OutputForm
  L      ==> List
  RN     ==> Fraction Integer
  ST     ==> Stream
```

```

Exports ==> QuotientFieldCategory(PADIC) with
approximate: (% , I) -> RN
  ++ \spad{approximate(x,n)} returns a rational number y such that
  ++ \spad{y = x (mod p^n)}.
continuedFraction: % -> CF RN
  ++ \spad{continuedFraction(x)} converts the p-adic rational number x
  ++ to a continued fraction.
removeZeroes: % -> %
  ++ \spad{removeZeroes(x)} removes leading zeroes from the
  ++ representation of the p-adic rational \spad{x}.
  ++ A p-adic rational is represented by (1) an exponent and
  ++ (2) a p-adic integer which may have leading zero digits.
  ++ When the p-adic integer has a leading zero digit, a 'leading zero'
  ++ is removed from the p-adic rational as follows:
  ++ the number is rewritten by increasing the exponent by 1 and
  ++ dividing the p-adic integer by p.
  ++ Note: \spad{removeZeroes(f)} removes all leading zeroes from f.
removeZeroes: (I,% ) -> %
  ++ \spad{removeZeroes(n,x)} removes up to n leading zeroes from
  ++ the p-adic rational \spad{x}.

Implementation ==> add

=====
PartialFraction examples
=====

```

A partial fraction is a decomposition of a quotient into a sum of quotients where the denominators of the summands are powers of primes. Most people first encounter partial fractions when they are learning integral calculus. For a technical discussion of partial fractions, see, for example, Lang's Algebra. For example, the rational number $1/6$ is decomposed into $1/2-1/3$. You can compute partial fractions of quotients of objects from domains belonging to the category EuclideanDomain. For example, Integer, Complex Integer, and UnivariatePolynomial(x, Fraction Integer) all belong to EuclideanDomain. In the examples following, we demonstrate how to decompose quotients of each of these kinds of object into partial fractions.

It is necessary that we know how to factor the denominator when we want to compute a partial fraction. Although the interpreter can often do this automatically, it may be necessary for you to include a call to factor. In these examples, it is not necessary to factor the denominators explicitly.

The main operation for computing partial fractions is called partialFraction

and we use this to compute a decomposition of $1/10!$. The first argument to `partialFraction` is the numerator of the quotient and the second argument is the factored denominator.

```
partialFraction(1,factorial 10)
159 23 12 1
--- - -- - -- + -
 8 4 2 7
2 3 5
Type: PartialFraction Integer
```

Since the denominators are powers of primes, it may be possible to expand the numerators further with respect to those primes. Use the operation `padicFraction` to do this.

```
f := padicFraction(%)
1 1 1 1 1 1 2 1 2 2 2 1
- + -- + -- + -- + -- + -- - - - - - - - - - - + -
2 4 5 6 7 8 2 3 4 5 2 7
2 2 2 2 2 3 3 3 5
Type: PartialFraction Integer
```

The operation `compactFraction` returns an expanded fraction into the usual form. The compacted version is used internally for computational efficiency.

```
compactFraction(f)
159 23 12 1
--- - -- - -- + -
 8 4 2 7
2 3 5
Type: PartialFraction Integer
```

You can add, subtract, multiply and divide partial fractions. In addition, you can extract the parts of the decomposition. `numberOfFractionalTerms` computes the number of terms in the fractional part. This does not include the whole part of the fraction, which you get by calling `wholePart`. In this example, the whole part is just 0.

```
numberOfFractionalTerms(f)
12
Type: PositiveInteger
```

The operation `nthFractionalTerm` returns the individual terms in the decomposition. Notice that the object returned is a partial fraction itself. `firstNumer` and `firstDenom` extract the numerator and denominator of the first term of the fraction.

```
nthFractionalTerm(f,3)
1
--
```

$$\frac{5}{2}$$

Type: PartialFraction Integer

Given two gaussian integers, you can decompose their quotient into a partial fraction.

$$\text{partialFraction}(1, -13 + 14 * \%i)$$

$$-\frac{1}{1 + 2\%i} + \frac{4}{3 + 8\%i}$$

Type: PartialFraction Complex Integer

To convert back to a quotient, simply use a conversion.

$$\% :: \text{Fraction Complex Integer}$$

$$-\frac{\%i}{14 + 13\%i}$$

Type: Fraction Complex Integer

To conclude this section, we compute the decomposition of

$$\frac{1}{(x + 1)(x + 2)(x + 3)(x + 4)}$$

The polynomials in this object have type UnivariatePolynomial(x, Fraction Integer).

We use the primeFactor operation to create the denominator in factored form directly.

$$u : \text{FR UP}(x, \text{FRAC INT}) := \text{reduce}(*, [\text{primeFactor}(x+i, i) \text{ for } i \text{ in } 1..4])$$

$$(x + 1)(x + 2)(x + 3)(x + 4)$$

Type: Factored UnivariatePolynomial(x, Fraction Integer)

These are the compact and expanded partial fractions for the quotient.

$$\text{partialFraction}(1, u)$$

$$\frac{1}{648} - \frac{1}{4}x + \frac{7}{16}x^2 - \frac{17}{8}x^3 - 12x^4 - \frac{139}{8}x^5 + \frac{607}{324}x^6 + \frac{10115}{432}x^7 + \frac{2}{4}x^8 + \frac{391}{4}x^9 + \frac{44179}{324}x^{10}$$

$$-\frac{1}{x + 1} + \frac{1}{(x + 2)^2} + \frac{7}{(x + 3)^3} + \frac{139}{(x + 4)^4}$$

Type: PartialFraction UnivariatePolynomial(x, Fraction Integer)

```

padicFraction %
      1      1      1      17      3      1      607      403

— domain PFR PartialFraction —

```

)abbrev domain PFR PartialFraction
++ Author: Robert S. Suttor
++ Date Created: 1986
++ Change History: 05/20/91 BMT Converted to the new library
++ Description:
++ The domain \spadtype{PartialFraction} implements partial fractions
++ over a euclidean domain \spad{R}. This requirement on the
++ argument domain allows us to normalize the fractions. Of
++ particular interest are the 2 forms for these fractions. The
++ ‘compact’ form has only one fractional term per prime in the
++ denominator, while the ‘p-adic’ form expands each numerator
++ p-adically via the prime p in the denominator. For computational
++ efficiency, the compact form is used, though the p-adic form may
++ be gotten by calling the function padicFraction}. For a
++ general euclidean domain, it is not known how to factor the
++ denominator. Thus the function partialFraction takes as its
++ second argument an element of \spadtype{Factored(R)}.

PartialFraction(R: EuclideanDomain): Cat == Capsule where
  FRR ==> Factored R
  SUPR ==> SparseUnivariatePolynomial R

Cat == Join(Field, Algebra R) with
  coerce: % -> Fraction R
  ++ coerce(p) sums up the components of the partial fraction and
  ++ returns a single fraction.
  ++
  ++X a:=(13/74)::PFR(INT)
  ++X a::FRAC(INT)

coerce: Fraction FRR -> %
  ++ coerce(f) takes a fraction with numerator and denominator in
  ++ factored form and creates a partial fraction. It is

```

```

++ necessary for the parts to be factored because it is not
++ known in general how to factor elements of \spad{R} and
++ this is needed to decompose into partial fractions.
++
++X (13/74)::PFR(INT)

compactFraction: % -> %
++ compactFraction(p) normalizes the partial fraction \spad{p}
++ to the compact representation. In this form, the partial
++ fraction has only one fractional term per prime in the
++ denominator.
++
++X a:=partialFraction(1,factorial 10)
++X b:=padicFraction(a)
++X compactFraction(b)

firstDenom: % -> FRR
++ firstDenom(p) extracts the denominator of the first fractional
++ term. This returns 1 if there is no fractional part (use
++ wholePart from PartialFraction to get the whole part).
++
++X a:=partialFraction(1,factorial 10)
++X firstDenom(a)

firstNumer: % -> R
++ firstNumer(p) extracts the numerator of the first fractional
++ term. This returns 0 if there is no fractional part (use
++ wholePart from PartialFraction to get the whole part).
++
++X a:=partialFraction(1,factorial 10)
++X firstNumer(a)

nthFractionalTerm: (%,Integer) -> %
++ nthFractionalTerm(p,n) extracts the nth fractional term from
++ the partial fraction \spad{p}. This returns 0 if the index
++ \spad{n} is out of range.
++
++X a:=partialFraction(1,factorial 10)
++X b:=padicFraction(a)
++X nthFractionalTerm(b,3)

numberOfFractionalTerms: % -> Integer
++ numberOfFractionalTerms(p) computes the number of fractional
++ terms in \spad{p}. This returns 0 if there is no fractional
++ part.
++
++X a:=partialFraction(1,factorial 10)
++X b:=padicFraction(a)
++X numberOfFractionalTerms(b)

```

```

padicallyExpand: (R,R) -> SUPR
  ++ padicallyExpand(p,x) is a utility function that expands
  ++ the second argument \spad{x} 'p-adically' in
  ++ the first.

padicFraction: % -> %
  ++ padicFraction(q) expands the fraction p-adically in the primes
  ++ \spad{p} in the denominator of \spad{q}. For example,
  ++ \spad{padicFraction(3/(2**2)) = 1/2 + 1/(2**2)}.
  ++ Use compactFraction from PartialFraction to
  ++ return to compact form.
  ++
  ++X a:=partialFraction(1,factorial 10)
  ++X padicFraction(a)

partialFraction: (R, FRR) -> %
  ++ partialFraction(num,denom) is the main function for
  ++ constructing partial fractions. The second argument is the
  ++ denominator and should be factored.
  ++
  ++X partialFraction(1,factorial 10)

wholePart: % -> R
  ++ wholePart(p) extracts the whole part of the partial fraction
  ++ \spad{p}.
  ++
  ++X a:=(74/13)::PFR(INT)
  ++X wholePart(a)

```

```

++ Reference: G. James/A. Kerber: The Representation Theory of the Symmetric
++ Group. Encycl. of Math. and its Appl., Vol. 16., Cambridge
++ Description:
++ Permutation(S) implements the group of all bijections
++ on a set S, which move only a finite number of points.
++ A permutation is considered as a map from S into S. In particular
++ multiplication is defined as composition of maps:\br
++ pi1 * pi2 = pi1 o pi2.\br
++ The internal representation of permutations are two lists
++ of equal length representing preimages and images.

```

PermutationGroup examples

=====

PermutationGroup implements permutation groups acting on a set S, i.e. all subgroups of the symmetric group of S, represented as a list of permutations (generators). Note that therefore the objects are not members of the Axiom category Group.

Using the idea of base and strong generators by Sims, basic routines and algorithms are implemented so that the word problem for permutation groups can be solved.

```
x : PERM INT := [[1,3,5],[7,11,9]]
```

```
(1 3 5)(7 11 9)
```

```
y : PERM INT := [[3,5,7,9]]
```

```
(3 5 7 9)
```

```
z : PERM INT := [1,3,11]
```

```
(1 3 11)
```

```
g1 : PERMGRP INT := [ x , y ]
```

```
<(1 3 5)(7 11 9),(3 5 7 9)>
```

```
g2 : PERMGRP INT := [ x , z ]
```

```
<(1 3 5)(7 11 9),(1 3 11)>
```

```
g3 : PERMGRP INT := [ y , z ]
```

```
<(3 5 7 9),(1 3 11)>
```

```
order g1
```

```
720
```

```
degree g3
```

```
6
```

```
movedPoints g2
```

```
{1,3,5,7,9,11}
```

```
orbit (g1, 3)
```

```

{1,3,5,7,9,11}

orbits g3

{{1,3,5,7,9,11}}

member? ( y , g2 )

++ movedPoints(gp) returns the points moved by the group gp.
++
++X x : PERM INT := [[1,3,5],[7,11,9]]
++X z : PERM INT := [1,3,11]
++X g : PERMGRP INT := [ x , z ]
++X movedPoints g

"<"          : (%,%)    -> B
++ gp1 < gp2 returns true if and only if gp1
++ is a proper subgroup of gp2.

"<="        : (%,%)    -> B
++ gp1 <= gp2 returns true if and only if gp1
++ is a subgroup of gp2.
++ Note: because of a bug in the parser you have to call this
++ function explicitly by gp1 <=$(PERMGRP S) gp2.
-- (GILT DAS NOCH?)

initializeGroupForWordProblem : %    -> Void
++ initializeGroupForWordProblem(gp) initializes the group gp
++ for the word problem.
++ Notes: it calls the other function of this name with parameters
++ 0 and 1: initializeGroupForWordProblem(gp,0,1).
++ Notes: (1) be careful: invoking this routine will destroy the
++ possibly information about your group (but will recompute it again)
++ (2) users need not call this function normally for the solution of
++ the word problem.

initializeGroupForWordProblem :(% ,I,I) -> Void
++ initializeGroupForWordProblem(gp,m,n) initializes the group
++ gp for the word problem.
++ Notes: (1) with a small integer you get shorter words, but the
++ routine takes longer than the standard routine for longer words.
++ (2) be careful: invoking this routine will destroy the possibly stored
++ information about your group (but will recompute it again).
++ (3) users need not call this function normally for the solution of
++ the word problem.

domain HACKPI Pi

What is the purpose of the HACKPI domain?

HACKPI is a hack provided for the benefit of the axiom interpreter. As a mathematical type, it is the simple transcendental extension $\mathbb{Q}(\pi)$ of the rational numbers. This type allows interactive users to use the name '%pi' without a type both where a numerical value is expected [as in `draw(sin x,x=-%pi..%pi)`] or when the exact symbolic value is meant. The interpreter defaults a typeless %pi to HACKPI and then uses the various conversions to cast it further as required by the context.

One could argue that it is unfair to single %pi out from other constants, but it occurs frequently enough in school examples (specially for graphs) so it was worth a special hack. In a non-interactive environment (library), HACKPI would not exist.

(Manuel Bronstein)

```
)abbrev domain ACPLOT PlaneAlgebraicCurvePlot
++ Author: Clifton J. Williamson and Timothy Daly
++ Date Created: Fall 1988
++ Date Last Updated: 27 April 1990
++ Description:
++ Plot a NON-SINGULAR plane algebraic curve  $p(x,y) = 0$ .
```

```

PlaneAlgebraicCurvePlot(): PlottablePlaneCurveCategory _
with

makeSketch:(Polynomial Integer,Symbol,Symbol,Segment Fraction Integer, _
             Segment Fraction Integer) -> %
++ makeSketch(p,x,y,a..b,c..d) creates an ACLOT of the
++ curve \spad{p = 0} in the region a <= x <= b, c <= y <= d.
++ More specifically, 'makeSketch' plots a non-singular algebraic curve
++ \spad{p = 0} in an rectangular region xMin <= x <= xMax,
++ yMin <= y <= yMax. The user inputs
++ \spad{makeSketch(p,x,y,xMin..xMax,yMin..yMax)}.
++ Here p is a polynomial in the variables x and y with
++ integer coefficients (p belongs to the domain
++ \spad{Polynomial Integer}). The case
++ where p is a polynomial in only one of the variables is
++ allowed. The variables x and y are input to specify the
++ the coordinate axes. The horizontal axis is the x-axis and
++ the vertical axis is the y-axis. The rational numbers
++ xMin,...,yMax specify the boundaries of the region in
++ which the curve is to be plotted.
++
++X makeSketch(x+y,x,y,-1/2..1/2,-1/2..1/2)$ACLOT

refine:(%,DoubleFloat) -> %
++ refine(p,x) is not documented
++
++X sketch:=makeSketch(x+y,x,y,-1/2..1/2,-1/2..1/2)$ACLOT
++X refined:=refine(sketch,0.1)

=====
Plot examples
=====
```

The Plot (PLOT) domain supports plotting of functions defined over a real number system. Plot is limited to 2 dimensional plots.

The function plot: (F -> F,R) -> % plots the function f(x) on the interval a..b. So we need to define a function that maps from DoubleFloat to DoubleFloat:

```
fp:=(t:DFLOAT):DFLOAT +-> sin(t)
```

and then feed it to the plot function with a Segment DoubleFloat

```
plot(fp,-1.0..1.0)$PLOT
```

)abbrev domain PLOT Plot
++ Author: Michael Monagan (revised by Clifton J. Williamson)
++ Date Created: Jan 1988
++ Date Last Updated: 30 Nov 1990 by Jonathan Steinbach
++ Description:
++ The Plot domain supports plotting of functions defined over a
++ real number system. A real number system is a model for the real
++ numbers and as such may be an approximation. For example
++ floating point numbers and infinite continued fractions.
++ The facilities at this point are limited to 2-dimensional plots
++ or either a single function or a parametric function.

Plot(): Exports == Implementation where

```

plot: (L(F -> F),R) -> %
  ++ plot([f1,...,fm],a..b) plots the functions \spad{y = f1(x)},...,
  ++ \spad{y = fm(x)} on the interval \spad{a..b}.
plot: (L(F -> F),R,R) -> %
  ++ plot([f1,...,fm],a..b,c..d) plots the functions \spad{y = f1(x)},...,
  ++ \spad{y = fm(x)} on the interval \spad{a..b}; y-range of \spad{[c,d]} is
  ++ noted in Plot object.

--% parametric plots

plot: (F -> F,F -> F,R) -> %
  ++ plot(f,g,a..b) plots the parametric curve \spad{x = f(t)},
  ++ \spad{y = g(t)} as t ranges over the interval \spad{[a,b]}.
plot: (F -> F,F -> F,R,R,R) -> %
  ++ plot(f,g,a..b,c..d,e..f) plots the parametric curve \spad{x = f(t)},
  ++ \spad{y = g(t)} as t ranges over the interval \spad{[a,b]}; x-range
  ++ of \spad{[c,d]} and y-range of \spad{[e,f]} are noted in Plot object.

--% parametric plots

pointPlot: (F -> P,R) -> %
  ++ pointPlot(t +-> (f(t),g(t)),a..b) plots the parametric curve
  ++ \spad{x = f(t)}, \spad{y = g(t)} as t ranges over the interval
  ++ \spad{[a,b]}.
pointPlot: (F -> P,R,R,R,R) -> %
  ++ pointPlot(t +-> (f(t),g(t)),a..b,c..d,e..f) plots the parametric
  ++ curve \spad{x = f(t)}, \spad{y = g(t)} as t ranges over the interval
  ++ \spad{[a,b]}; x-range of \spad{[c,d]} and y-range of \spad{[e,f]}
  ++ are noted in Plot object.

--% polar plots

plotPolar: (F -> F,R) -> %
  ++ plotPolar(f,a..b) plots the polar curve \spad{r = f(theta)} as
  ++ theta ranges over the interval \spad{[a,b]}; this is the same as
  ++ the parametric curve \spad{x = f(t)*cos(t)}, \spad{y = f(t)*sin(t)}.

plotPolar: (F -> F) -> %
  ++ plotPolar(f) plots the polar curve \spad{r = f(theta)} as theta
  ++ ranges over the interval \spad{[0,2*pi]}; this is the same as
  ++ the parametric curve \spad{x = f(t)*cos(t)}, \spad{y = f(t)*sin(t)}.

plot: (% ,R) -> %          -- change the range
  ++ plot(x,r) is not documented
parametric?: % -> B
  ++ parametric? determines whether it is a parametric plot?

zoom: (% ,R) -> %
  ++ zoom(x,r) is not documented

```

```

zoom: (%R,R) -> %
  ++ zoom(x,r,s) is not documented
refine: (%R) -> %
  ++ refine(x,r) is not documented
refine: % -> %
  ++ refine(p) performs a refinement on the plot p

tRange: % -> R
  ++ tRange(p) returns the range of the parameter in a parametric plot p

minPoints: () -> I
  ++ minPoints() returns the minimum number of points in a plot
setMinPoints: I -> I
  ++ setMinPoints(i) sets the minimum number of points in a plot to i
maxPoints: () -> I
  ++ maxPoints() returns the maximum number of points in a plot
setMaxPoints: I -> I
  ++ setMaxPoints(i) sets the maximum number of points in a plot to i
screenResolution: () -> I
  ++ screenResolution() returns the screen resolution
setScreenResolution: I -> I
  ++ setScreenResolution(i) sets the screen resolution to i
adaptive?: () -> B
  ++ adaptive?() determines whether plotting be done adaptively
setAdaptive: B -> B
  ++ setAdaptive(true) turns adaptive plotting on
  ++ \spad{setAdaptive(false)} turns adaptive plotting off
numFunEvals: () -> I
  ++ numFunEvals() returns the number of points computed
debug: B -> B
  ++ debug(true) turns debug mode on
  ++ \spad{debug(false)} turns debug mode off

Plot3D examples

Plot3D supports parametric plots defined over a real number system. A real number system is a model for the real numbers and as such may be an approximation. For example, floating point numbers and infinite continued fractions are real number systems. The facilities at this point are limited to 3-dimensional parametric plots.

)abbrev domain PLOT3D Plot3D
++ Author: Clifton J. Williamson based on code by Michael Monagan
++ Date Created: Jan 1989
++ Date Last Updated: 22 November 1990 (Jon Steinbach)
++ Description:
++ Plot3D supports parametric plots defined over a real
++ number system. A real number system is a model for the real
++ numbers and as such may be an approximation. For example,
++ floating point numbers and infinite continued fractions are
++ real number systems. The facilities at this point are limited
++ to 3-dimensional parametric plots.

Plot3D(): Exports == Implementation where
  B ==> Boolean
  F ==> DoubleFloat
  I ==> Integer
  L ==> List
  N ==> NonNegativeInteger
  OUT ==> OutputForm
  P ==> Point F
  S ==> String
  R ==> Segment F
  O ==> OutputPackage
  C ==> Record(source: F -> P, ranges: L R, knots: L F, points: L P)

Exports ==> PlottableSpaceCurveCategory with

```

```

pointPlot: (F -> P,R) -> %
  ++ pointPlot(f,g,h,a..b) plots {/emx = f(t), y = g(t), z = h(t)} as
  ++ t ranges over {/em[a,b]}.
pointPlot: (F -> P,R,R,R,R) -> %
  ++ pointPlot(f,x,y,z,w) is not documented
plot: (F -> F,F -> F,F -> F,F -> F,R) -> %
  ++ plot(f,g,h,a..b) plots {/emx = f(t), y = g(t), z = h(t)} as
  ++ t ranges over {/em[a,b]}.
plot: (F -> F,F -> F,F -> F,F -> F,R,R,R,R) -> %
  ++ plot(f1,f2,f3,f4,x,y,z,w) is not documented

plot: (% ,R) -> %          -- change the range
  ++ plot(x,r) is not documented
zoom: (% ,R,R,R) -> %
  ++ zoom(x,r,s,t) is not documented
refine: (% ,R) -> %
  ++ refine(x,r) is not documented
refine: % -> %
  ++ refine(x) is not documented

tRange: % -> R
  ++ tRange(p) returns the range of the parameter in a parametric plot p.
tValues: % -> L L F
  ++ tValues(p) returns a list of lists of the values of the parameter for
  ++ which a point is computed, one list for each curve in the plot p.

minPoints3D: () -> I
  ++ minPoints3D() returns the minimum number of points in a plot.
setMinPoints3D: I -> I
  ++ setMinPoints3D(i) sets the minimum number of points in a plot to i.
maxPoints3D: () -> I
  ++ maxPoints3D() returns the maximum number of points in a plot.
setMaxPoints3D: I -> I
  ++ setMaxPoints3D(i) sets the maximum number of points in a plot to i.
screenResolution3D: () -> I
  ++ screenResolution3D() returns the screen resolution for a 3d graph.
setScreenResolution3D: I -> I
  ++ setScreenResolution3D(i) sets the screen resolution for a 3d graph to i.
adaptive3D?: () -> B
  ++ adaptive3D?() determines whether plotting be done adaptively.
setAdaptive3D: B -> B
  ++ setAdaptive3D(true) turns adaptive plotting on;
  ++ setAdaptive3D(false) turns adaptive plotting off.
numFunEvals3D: () -> I
  ++ numFunEvals3D() returns the number of points computed.
debug3D: B -> B
  ++ debug3D(true) turns debug mode on;
  ++ debug3D(false) turns debug mode off.

```

```

=====
Polynomial examples
=====

The domain constructor Polynomial (abbreviation: POLY) provides polynomials with an arbitrary number of unspecified variables.

It is used to create the default polynomial domains in Axiom. Here the coefficients are integers.

```

x + 1
x + 1
                                Type: Polynomial Integer

```

Here the coefficients have type Float.

```

z - 2.3
z - 2.3
                                Type: Polynomial Float

```

And here we have a polynomial in two variables with coefficients which

have type Fraction Integer.

$$y^{**2} - z + \frac{3}{4} \\ - z + y^2 + \frac{3}{4}$$

Type: Polynomial Fraction Integer

The representation of objects of domains created by Polynomial is that of recursive univariate polynomials. The term univariate means "one variable". The term multivariate means "possibly more than one variable".

This recursive structure is sometimes obvious from the display of a polynomial.

$$y^{**2} + x*y + y \\ y^2 + (x + 1)y$$

Type: Polynomial Integer

In this example, you see that the polynomial is stored as a polynomial in y with coefficients that are polynomials in x with integer coefficients. In fact, you really don't need to worry about the representation unless you are working on an advanced application where it is critical. The polynomial types created from DistributedMultivariatePolynomial and NewDistributedMultivariatePolynomial are stored and displayed in a non-recursive manner.

You see a "flat" display of the above polynomial by converting to one of those types.

$$\% :: \text{DMP}([y,x],\text{INT}) \\ y^2 + yx + y$$

Type: DistributedMultivariatePolynomial([y,x],Integer)

We will demonstrate many of the polynomial facilities by using two polynomials with integer coefficients.

By default, the interpreter expands polynomial expressions, even if they are written in a factored format.

$$p := (y-1)^{**2} * x * z \\ (x y^2 - 2x y + x)z$$

Type: Polynomial Integer

See Factored to see how to create objects in factored form directly.

$$q := (y-1) * x * (z+5) \\ (x y - x)z + 5x y - 5x$$

Type: Polynomial Integer

The fully factored form can be recovered by using factor.

```
factor(q)
x(y - 1)(z + 5)
Type: Factored Polynomial Integer
```

This is the same name used for the operation to factor integers. Such reuse of names is called overloading and makes it much easier to think of solving problems in general ways. Axiom facilities for factoring polynomials created with Polynomial are currently restricted to the integer and rational number coefficient cases.

The standard arithmetic operations are available for polynomials.

```
p - q**2
      2 2      2      2 2      2      2      2      2
      (- x y + 2x y - x )z + ((- 10x + x)y + (20x - 2x)y - 10x + x)z
+
      2 2      2      2
      - 25x y + 50x y - 25x
Type: Polynomial Integer
```

The operation gcd is used to compute the greatest common divisor of two polynomials.

```
gcd(p,q)
x y - x
Type: Polynomial Integer
```

In the case of p and q, the gcd is obvious from their definitions. We factor the gcd to show this relationship better.

```
factor %
x(y - 1)
Type: Factored Polynomial Integer
```

The least common multiple is computed by using lcm.

```
lcm(p,q)
      2      2      2
      (x y - 2x y + x)z + (5x y - 10x y + 5x)z
Type: Polynomial Integer
```

Use content to compute the greatest common divisor of the coefficients of the polynomial.

```
content p
1
```

Type: PositiveInteger

Many of the operations on polynomials require you to specify a variable. For example, `resultant` requires you to give the variable in which the polynomials should be expressed.

This computes the resultant of the values of `p` and `q`, considering them as polynomials in the variable `z`. They do not share a root when thought of as polynomials in `z`.

```
resultant(p,q,z)
  2 3      2 2      2      2
  5x y  - 15x y  + 15x y  - 5x
                                     Type: Polynomial Integer
```

This value is 0 because as polynomials in `x` the polynomials have a common root.

```
resultant(p,q,x)
  0
                                     Type: Polynomial Integer
```

The data type used for the variables created by `Polynomial` is `Symbol`. As mentioned above, the representation used by `Polynomial` is recursive and so there is a main variable for nonconstant polynomials.

The operation `mainVariable` returns this variable. The return type is actually a union of `Symbol` and "failed".

```
mainVariable p
  z
                                     Type: Union(Symbol,...)
```

The latter branch of the union is be used if the polynomial has no variables, that is, is a constant.

```
mainVariable(1 :: POLY INT)
  "failed"
                                     Type: Union("failed",...)
```

You can also use the predicate `ground?` to test whether a polynomial is in fact a member of its ground ring.

```
ground? p
  false
                                     Type: Boolean
```

```
ground?(1 :: POLY INT)
  true
                                     Type: Boolean
```

The complete list of variables actually used in a particular polynomial is returned by `variables`. For constant polynomials, this list is empty.

```
variables p
  [z,y,x]
      Type: List Symbol
```

The `degree` operation returns the degree of a polynomial in a specific variable.

```
degree(p,x)
  1
      Type: PositiveInteger
```

```
degree(p,y)
  2
      Type: PositiveInteger
```

```
degree(p,z)
  1
      Type: PositiveInteger
```

If you give a list of variables for the second argument, a list of the degrees in those variables is returned.

```
degree(p,[x,y,z])
  [1,2,1]
      Type: List NonNegativeInteger
```

The minimum degree of a variable in a polynomial is computed using `minimumDegree`.

```
minimumDegree(p,z)
  1
      Type: PositiveInteger
```

The total degree of a polynomial is returned by `totalDegree`.

```
totalDegree p
  4
      Type: PositiveInteger
```

It is often convenient to think of a polynomial as a leading monomial plus the remaining terms.

```
leadingMonomial p
  2
  x y z
      Type: Polynomial Integer
```

The reductum operation returns a polynomial consisting of the sum of the monomials after the first.

```

reductum p
  (- 2x y + x)z
      Type: Polynomial Integer
    
```

These have the obvious relationship that the original polynomial is equal to the leading monomial plus the reductum.

```

p - leadingMonomial p - reductum p
  0
      Type: Polynomial Integer
    
```

The value returned by leadingMonomial includes the coefficient of that term. This is extracted by using leadingCoefficient on the original polynomial.

```

leadingCoefficient p
  1
      Type: PositiveInteger
    
```

The operation eval is used to substitute a value for a variable in a polynomial.

```

p
  2
  (x y - 2x y + x)z
      Type: Polynomial Integer
    
```

This value may be another variable, a constant or a polynomial.

```

eval(p,x,w)
  2
  (w y - 2w y + w)z
      Type: Polynomial Integer
    
```

```

eval(p,x,1)
  2
  (y - 2y + 1)z
      Type: Polynomial Integer
    
```

Actually, all the things being substituted are just polynomials, some more trivial than others.

```

eval(p,x,y^2 - 1)
  4      3
  (y - 2y + 2y - 1)z
      Type: Polynomial Integer
    
```

Derivatives are computed using the D operation.

```
D(p,x)
  2
  (y - 2y + 1)z
      Type: Polynomial Integer
```

The first argument is the polynomial and the second is the variable.

```
D(p,y)
  (2x y - 2x)z
      Type: Polynomial Integer
```

Even if the polynomial has only one variable, you must specify it.

```
D(p,z)
  2
  x y - 2x y + x
      Type: Polynomial Integer
```

Integration of polynomials is similar and the integrate operation is used.

Integration requires that the coefficients support division. Axiom converts polynomials over the integers to polynomials over the rational numbers before integrating them.

```
integrate(p,y)
  1 3 2
  (- x y - x y + x y)z
  3
      Type: Polynomial Fraction Integer
```

It is not possible, in general, to divide two polynomials. In our example using polynomials over the integers, the operation `monicDivide` divides a polynomial by a monic polynomial (that is, a polynomial with leading coefficient equal to 1). The result is a record of the quotient and remainder of the division.

You must specify the variable in which to express the polynomial.

```
qr := monicDivide(p,x+1,x)
  2 2
  [quotient= (y - 2y + 1)z,remainder= (- y + 2y - 1)z]
      Type: Record(quotient: Polynomial Integer,remainder: Polynomial Integer)
```

The selectors of the components of the record are `quotient` and `remainder`. Issue this to extract the remainder.

```
qr.remainder
  2
  (- y + 2y - 1)z
```

Type: Polynomial Integer

Now that we can extract the components, we can demonstrate the relationship among them and the arguments to our original expression
`qr := monicDivide(p,x+1,x).`

$$p - ((x+1) * qr.quotient + qr.remainder)$$

0

Type: Polynomial Integer

If the / operator is used with polynomials, a fraction object is created. In this example, the result is an object of type Fraction Polynomial Integer.

$$\frac{p/q}{(y - 1)z}$$

$$\frac{\quad}{z + 5}$$

Type: Fraction Polynomial Integer

If you use rational numbers as polynomial coefficients, the resulting object is of type Polynomial Fraction Integer.

$$(2/3) * x^{**2} - y + 4/5$$

$$- y + \frac{2}{3} x^2 + \frac{4}{5}$$

Type: Polynomial Fraction Integer

This can be converted to a fraction of polynomials and back again, if required.

$$\% :: \text{FRAC POLY INT}$$

$$\frac{-15y + 10x^2 + 12}{15}$$

Type: Fraction Polynomial Integer

$$\% :: \text{POLY FRAC INT}$$

$$- y + \frac{2}{3} x^2 + \frac{4}{5}$$

Type: Polynomial Fraction Integer

To convert the coefficients to floating point, map the numeric operation on the coefficients of the polynomial.

$$\text{map(numeric,\%)}$$

$$- 1.0 y + 0.6666666666666667 x^2 + 0.8$$

Type: Polynomial Float

PolynomialIdeals examples
=====

This domain represents polynomial ideals with coefficients in any field and supports the basic ideal operations, including intersection sum and quotient.

An ideal is represented by a list of polynomials (the generators of the ideal) and a boolean that is true if the generators are a Groebner basis.

The algorithms used are based on Groebner basis computations. The ordering is determined by the datatype of the input polynomials. Users may use refinements of total degree orderings.

leadingIdeal    :      Ideal      -> Ideal
++ leadingIdeal(I) is the ideal generated by the
++ leading terms of the elements of the ideal I.
ideal          :      List DPoly     -> Ideal
++ ideal(polyList) constructs the ideal generated by the list
++ of polynomials polyList.
groebnerIdeal  :      List DPoly     -> Ideal
++ groebnerIdeal(polyList) constructs the ideal generated by the list
++ of polynomials polyList which are assumed to be a Groebner
++ basis.
++ Note: this operation avoids a Groebner basis computation.
groebner?      :      Ideal      -> Boolean
++ groebner?(I) tests if the generators of the ideal I are a
++ Groebner basis.
generators     :      Ideal      -> List DPoly
++ generators(I) returns a list of generators for the ideal I.
coerce        :      List DPoly     -> Ideal
++ coerce(polyList) converts the list of polynomials polyList
++ to an ideal.

saturate       : (Ideal,DPoly)      -> Ideal
++ saturate(I,f) is the saturation of the ideal I
++ with respect to the multiplicative
++ set generated by the polynomial f.
saturate       :(Ideal,DPoly,List VarSet) -> Ideal
++ saturate(I,f,lvar) is the saturation with respect to the prime
++ principal ideal which is generated by f in the polynomial ring
++ \spad{F[lvar]}.
if VarSet has ConvertibleTo Symbol then
relationsIdeal :      List DPoly     -> ST
++ relationsIdeal(polyList) returns the ideal of relations among the
++ polynomials in polyList.

=====
PolynomialRing examples
=====

```

This domain represents generalized polynomials with coefficients (from a not necessarily commutative ring), and terms indexed by their exponents (from an arbitrary ordered abelian monoid).

This type is used, for example, by the DistributedMultivariatePolynomial domain where the exponent domain is a direct product of non negative integers.

=====
 Product examples
 =====

The direct product of two functions over the same domain is another function over that domain whose co-domain is the product of their co-domains.

So we can define two functions, f and g, that go from INT -> INT

```
f:=(x:INT):INT +-> 3*x
g:=(x:INT):INT +-> x^3
```

so

```
f(3) is 9
g(3) is 27
```

and we can construct the direct product of those functions h=f,g

```
h(x:INT):Product(INT,INT) == makeprod(f x, g x)
```

so

```
h(3) is (9,27)
```

PseudoAlgebraicClosureOfAlgExtOfRationalNumber examples
=====
```

This domain implement dynamic extension over the PseudoAlgebraicClosureOfRationalNumber.

A tower extension T of the ground field K is any sequence of field extension

($T : K_0, K_1, \dots, K_i, \dots, K_n$)
 where $K_0 = K$ and for $i = 1, 2, \dots, n$, K_i is an extension of K_{i-1} of degree > 1 and defined by an irreducible polynomial $p(Z)$ in K_{i-1} .

Two towers

($T_1: K_{01}, K_{11}, \dots, K_{i1}, \dots, K_{n1}$)
 and

($T_2: K_{02}, K_{12}, \dots, K_{i2}, \dots, K_{n2}$)

are said to be related if

$T_1 \leq T_2$ (or $T_1 \geq T_2$),

that is if

$K_{i1} = K_{i2}$ for $i=1, 2, \dots, n1$

(or $i=1, 2, \dots, n2$). Any algebraic operations defined for several elements are only defined if all of the concerned elements are coming from a set of related tower extensions.

=====
PseudoAlgebraicClosureOfRationalNumber examples
=====

```

This domain implements dynamic extension using the simple notion of tower extensions. A tower extension T of the ground field K is any sequence of field extension

$$(T : K_0, K_1, \dots, K_i, \dots, K_n)$$

where $K_0 = K$ and for $i = 1, 2, \dots, n$, K_i is an extension of K_{i-1} of degree > 1 and defined by an irreducible polynomial $p(Z)$ in K_{i-1} .

Two towers

$$(T_1: K_{01}, K_{11}, \dots, K_{i1}, \dots, K_{n1})$$

and

$$(T_2: K_{02}, K_{12}, \dots, K_{i2}, \dots, K_{n2})$$

are said to be related if

$$T_1 \leq T_2 \text{ (or } T_1 \geq T_2),$$

that is if

$$K_{i1} = K_{i2} \text{ for } i=1, 2, \dots, n1 \text{ (or } i=1, 2, \dots, n2).$$

Any algebraic operations defined for several elements are only defined if all of the concerned elements are coming from a set of related tower extensions.

++ Date Created: feb 1997
++ Date Last Updated: May 2010 by Tim Daly
++ Description:
++ This domain implements dynamic extension using the simple notion of
++ tower extensions. A tower extension T of the ground field K is any
++ sequence of field extension (T : K_0, K_1, ..., K_i...,K_n) where K_0 = K
++ and for i =1,2,...,n, K_i is an extension of K_{i-1} of degree > 1 and
++ defined by an irreducible polynomial p(Z) in K_{i-1}.
++ Two towers (T_1: K_01, K_11,...,K_i1,...,K_n1) and
++ (T_2: K_02, K_12,...,K_i2,...,K_n2) are said to be related if T_1 <= T_2
++ (or T_1 >= T_2), that is if K_i1 = K_i2 for i=1,2,...,n1
++ (or i=1,2,...,n2). Any algebraic operations defined for several elements
++ are only defined if all of the concerned elements are coming from
++ a set of related tower extensions.

=====
QuasiAlgebraicSet examples
=====

```

QuasiAlgebraicSet constructs a domain representing quasi-algebraic sets, which is the intersection of a Zariski closed set, defined as the common zeros of a given list of polynomials (the defining polynomials for equations), and a principal Zariski open set, defined as the complement of the common zeros of a polynomial f (the defining polynomial for the inequation).

This domain provides simplification of a user-given representation using groebner basis computations.

There are two simplification routines: the first function `idealSimplify` uses groebner basis of ideals alone, while the second, `simplify` uses both groebner basis and factorization. The resulting defining equations `L` always form a groebner basis, and the resulting defining inequation `f` is always reduced. The function `simplify` may be applied several times if desired. A third simplification routine `radicalSimplify` is provided in `QuasiAlgebraicSet2` for comparison study only, as it is inefficient compared to the other two, as well as is restricted to only certain coefficient domains. For detail analysis and a comparison of the three methods, please consult the reference cited.

A polynomial function `q` defined on the quasi-algebraic set is equivalent to its reduced form with respect to `L`. While this may be obtained using the usual normal form algorithm, there is no canonical form for `q`.

The ordering in groebner basis computation is determined by the data type of the input polynomials. If it is possible we suggest to use refinements of total degree orderings.

— Quaternion.help —

=====

Quaternion examples

=====

The domain constructor Quaternion implements quaternions over commutative rings.

The basic operation for creating quaternions is quatern. This is a quaternion over the rational numbers.

```

q := quatern(2/11,-8,3/4,1)
      2      3
-- - 8i + - j + k
      11     4
Type: Quaternion Fraction Integer

```

The four arguments are the real part, the i imaginary part, the j imaginary part, and the k imaginary part, respectively.

```

[real q, imagI q, imagJ q, imagK q]
      2      3
[--, - 8, -, 1]
      11     4
Type: List Fraction Integer

```

Because q is over the rationals (and nonzero), you can invert it.

```

inv q
      352      15488      484      1936
----- + ----- i - ----- j - ----- k
126993  126993  42331  126993

```

Type: Quaternion Fraction Integer

The usual arithmetic (ring) operations are available

```

q^6
  2029490709319345   48251690851   144755072553   48251690851
  - ----- - ----- i + ----- j + ----- k
      7256313856       1288408       41229056       10307264
Type: Quaternion Fraction Integer
    
```

```

r := quatern(-2,3,23/9,-89); q + r
  20       119
  - -- - 5i + --- j - 88k
  11       36
Type: Quaternion Fraction Integer
    
```

In general, multiplication is not commutative.

```

q * r - r * q
  2495           817
  - ---- i - 1418j - --- k
   18           18
Type: Quaternion Fraction Integer
    
```

There are no predefined constants for the imaginary i, j, and k parts, but you can easily define them.

```

i:=quatern(0,1,0,0)
i
Type: Quaternion Integer
    
```

```

j:=quatern(0,0,1,0)
j
Type: Quaternion Integer
    
```

```

k:=quatern(0,0,0,1)
k
Type: Quaternion Integer
    
```

These satisfy the normal identities.

```

[i*i, j*j, k*k, i*j, j*k, k*i, q*i]
  2           3
  [- 1,- 1,- 1,k,i,j,8 + -- i + j - - k]
  11          4
Type: List Quaternion Fraction Integer
    
```

The norm is the quaternion times its conjugate.

```

norm q
    
```

```

126993
-----
1936

```

Type: Fraction Integer

```

conjugate q
      2      3
-- + 8i - - j - k
11      4

```

Type: Quaternion Fraction Integer

```

q * %
126993
-----
1936

```

Type: Quaternion Fraction Integer

=====
Queue examples
=====

```

A Queue object is represented as a list ordered by first-in, first-out. It operates like a line of people, where the "next" person is the one at the front of the line.

Here we create an queue of integers from a list. Notice that the order in the list is the order in the queue.

```
a:Queue INT:= queue [1,2,3,4,5]
  [1,2,3,4,5]
```

We can remove the top of the queue using dequeue!:

```
dequeue! a
  1
```

Notice that the use of dequeue! is destructive (destructive operations in Axiom usually end with ! to indicate that the underlying data structure is changed).

```
a
  [2,3,4,5]
```

The extract! operation is another name for the pop! operation and has the same effect. This operation treats the queue as a BagAggregate:

```
extract! a
  2
```

and you can see that it also has destructively modified the queue:

```
a
  [3,4,5]
```

Next we use enqueue! to add a new element to the end of the queue:

```
push!(9,a)
  9
```

Again, the push! operation is destructive so the queue is changed:

```
a
  [3,4,5,9]
```

Another name for enqueue! is insert!, which treats the queue as a BagAggregate:

```
insert!(8,a)
  [3,4,5,9,8]
```

and it modifies the queue:

```
a
  [3,4,5,9,8]
```

The inspect function returns the top of the queue without modification, viewed as a BagAggregate:

```
inspect a
8
```

The `empty?` operation returns true only if there are no element on the queue, otherwise it returns false:

```
empty? a
false
```

The `front` operation returns the front of the queue without modification:

```
front a
3
```

The `back` operation returns the back of the queue without modification:

```
back a
8
```

The `rotate!` operation moves the item at the front of the queue to the back of the queue:

```
rotate! a
[4,5,9,8,3]
```

The `#` (length) operation:

```
#a
5
```

The `length` operation does the same thing:

```
length a
5
```

The `less?` predicate will compare the queue length to an integer:

```
less?(a,9)
true
```

The `more?` predicate will compare the queue length to an integer:

```
more?(a,9)
false
```

The `size?` operation will compare the queue length to an integer:

```
size?(a,#a)
true
```

and since the last computation must always be true we try:

```
size?(a,9)
  false
```

The parts function will return the queue as a list of its elements:

```
parts a
  [8,9,3,4,5]
```

If we have a BagAggregate of elements we can use it to construct a queue:

```
bag([1,2,3,4,5])$Queue(INT)
  [1,2,3,4,5]
```

The empty function will construct an empty queue of a given type:

```
b:=empty()$(Queue INT)
  []
```

and the empty? predicate allows us to find out if a queue is empty:

```
empty? b
  true
```

The sample function returns a sample, empty queue:

```
sample()$Queue(INT)
  []
```

We can copy a queue and it does not share storage so subsequent modifications of the original queue will not affect the copy:

```
c:=copy a
  [4,5,9,8,3]
```

The eq? function is only true if the lists are the same reference, so even though c is a copy of a, they are not the same:

```
eq?(a,c)
  false
```

However, a clearly shares a reference with itself:

```
eq?(a,a)
  true
```

But we can compare a and c for equality:

```
(a=c)@Boolean
```

```
true
```

and clearly a is equal to itself:

```
(a=a)@Boolean
true
```

and since a and c are equal, they are clearly NOT not-equal:

```
a~c
false
```

We can use the any? function to see if a predicate is true for any element:

```
any?(x+-(x=4),a)
true
```

or false for every element:

```
any?(x+-(x=11),a)
false
```

We can use the every? function to check every element satisfies a predicate:

```
every?(x+-(x=11),a)
false
```

We can count the elements that are equal to an argument of this type:

```
count(4,a)
1
```

or we can count against a boolean function:

```
count(x+-(x>2),a)
5
```

You can also map a function over every element, returning a new queue:

```
map(x+->x+10,a)
[14,15,19,18,13]
```

Notice that the original queue is unchanged:

```
a
[4,5,9,8,3]
```

You can use map! to map a function over every element and change the original queue since map! is destructive:

```
map!(x+>x+10,a)
[14,15,19,18,13]
```

o

Notice that the original queue has been changed:

```
a
[14,15,19,18,13]
```

The member function can also get the element of the queue as a list:

```
members a
[18,19,13,14,15]
```

and using member? we can test if the queue holds a given element:

```
member?(14,a)
true
```

— RadixExpansion.help —

```

=====
RadixExpansion examples
=====

```

It possible to expand numbers in general bases.

Here we expand 111 in base 5. This means

$$10^2 + 10^1 + 10^0 = 4 * 5^2 + 2 * 5^1 + 5^0$$

```
111::RadixExpansion(5)
  421
```

Type: RadixExpansion 5

You can expand fractions to form repeating expansions.

```
(5/24)::RadixExpansion(2)
  0.00110
```

Type: RadixExpansion 2

```
(5/24)::RadixExpansion(3)
  0.012
```

Type: RadixExpansion 3

```
(5/24)::RadixExpansion(8)
  0.152
```

Type: RadixExpansion 8

```
(5/24)::RadixExpansion(10)
  0.2083
```

Type: RadixExpansion 10

For bases from 11 to 36 the letters A through Z are used.

```
(5/24)::RadixExpansion(12)
  0.26
```

Type: RadixExpansion 12

```
(5/24)::RadixExpansion(16)
  0.35
```

Type: RadixExpansion 16

```
(5/24)::RadixExpansion(36)
  0.7I
```

Type: RadixExpansion 36

For bases greater than 36, the digits are separated by blanks.

```
(5/24)::RadixExpansion(38)
  0 . 7 34 31 25 12
```

Type: RadixExpansion 38

The RadixExpansion type provides operations to obtain the individual ragits. Here is a rational number in base 8.

```
a := (76543/210)::RadixExpansion(8)
```

```
-----
554.37307
```

Type: RadixExpansion 8

The operation wholeRagits returns a list of the ragits for the integral part of the number.

```
w := wholeRagits a
[5,5,4]
```

Type: List Integer

The operations prefixRagits and cycleRagits return lists of the initial and repeating ragits in the fractional part of the number.

```
f0 := prefixRagits a
[3]
```

Type: List Integer

```
f1 := cycleRagits a
[7,3,0,7]
```

Type: List Integer

You can construct any radix expansion by giving the whole, prefix and cycle parts. The declaration is necessary to let Axiom know the base of the ragits.

```
u:RadixExpansion(8):=wholeRadix(w)+fractRadix(f0,f1)
```

```
-----
554.37307
```

Type: RadixExpansion 8

If there is no repeating part, then the list [0] should be used.

```
v: RadixExpansion(12) := fractRadix([1,2,3,11], [0])
```

```
-
0.123B0
```

Type: RadixExpansion 12

If you are not interested in the repeating nature of the expansion, an infinite stream of ragits can be obtained using fractRagits.

```
fractRagits(u)
```

```
-----
[3,7,3,0,7,7]
```

Type: Stream Integer

Of course, it's possible to recover the fraction representation:

```
a :: Fraction(Integer)
  76543
  ----
   210
```

Type: Fraction Integer

— domain RADIX RadixExpansion —

```
)abbrev domain RADIX RadixExpansion
++ Author: Stephen M. Watt
++ Date Created: October 1986
++ Date Last Updated: May 15, 1991
++ Description:
++ This domain allows rational numbers to be presented as repeating
++ decimal expansions or more generally as repeating expansions in any base.
```

```
RadixExpansion(bb): Exports == Implementation where
  bb : Integer
  I ==> Integer
  NNI ==> NonNegativeInteger
  OUT ==> OutputForm
  RN ==> Fraction Integer
  ST ==> Stream Integer
  QuoRem ==> Record(quotient: Integer, remainder: Integer)
```

```

Exports ==> QuotientFieldCategory(Integer) with
  coerce: % -> Fraction Integer
    ++ coerce(rx) converts a radix expansion to a rational number.
fractionPart: % -> Fraction Integer
    ++ fractionPart(rx) returns the fractional part of a radix expansion.
wholeRagits: % -> List Integer
    ++ wholeRagits(rx) returns the ragits of the integer part
    ++ of a radix expansion.
fractRagits: % -> Stream Integer
    ++ fractRagits(rx) returns the ragits of the fractional part
    ++ of a radix expansion.
prefixRagits: % -> List Integer
    ++ prefixRagits(rx) returns the non-cyclic part of the ragits
    ++ of the fractional part of a radix expansion.
    ++ For example, if \spad{x = 3/28 = 0.10 714285 714285 ...},
    ++ then \spad{prefixRagits(x)=[1,0]}.
cycleRagits: % -> List Integer
    ++ cycleRagits(rx) returns the cyclic part of the ragits of the
    ++ fractional part of a radix expansion.
    ++ For example, if \spad{x = 3/28 = 0.10 714285 714285 ...},
    ++ then \spad{cycleRagits(x) = [7,1,4,2,8,5]}.
wholeRadix: List Integer -> %
    ++ wholeRadix(l) creates an integral radix expansion from a list
    ++ of ragits.
    ++ For example, \spad{wholeRadix([1,3,4])} will return \spad{134}.
fractRadix: (List Integer, List Integer) -> %
    ++ fractRadix(pre,cyc) creates a fractional radix expansion
    ++ from a list of prefix ragits and a list of cyclic ragits.
    ++ e.g., \spad{fractRadix([1],[6])} will return \spad{0.16666666...}.

domain RECLOS RealClosure

The domain constructor **RealClosure** by Renaud Rioboo (University of Paris 6, France) provides the real closure of an ordered field. The implementation is based on interval arithmetic. Moreover, the design of this constructor and its related packages allows an easy use of other codings for real algebraic numbers. ordered field

The RealClosure domain is the end-user code, it provides usual arithmetics with real algebraic numbers, along with the functionalities of a real closed field. It also provides functions to approximate a real algebraic number by an element of the base field. This approximation may either be absolute (approximate) or relative (realtivApprox).

CAVEATS

Since real algebraic expressions are stored as depending on "real roots" which are managed like variables, there is an ordering on these. This ordering is dynamical in the sense that any

new algebraic takes precedence over older ones. In particular every creation function raises a new "real root". This has the effect that when you type something like `sqrt(2) + sqrt(2)` you have two new variables which happen to be equal. To avoid this name the expression such as in `s2 := sqrt(2) ; s2 + s2`

Also note that computing times depend strongly on the ordering you implicitly provide. Please provide algebraics in the order which most natural to you.

LIMITATIONS

The file `reclos.input` show some basic use of the package. This package uses algorithms which are published in [1] and [2] which are based on field arithmetics, in particular for polynomial gcd related algorithms. This can be quite slow for high degree polynomials and subresultants methods usually work best. Beta versions of the package try to use these techniques in a better way and work significantly faster. These are mostly based on unpublished algorithms and cannot be distributed. Please contact the author if you have a particular problem to solve or want to use these versions.

Be aware that approximations behave as post-processing and that all computations are done exactly. They can thus be quite time consuming when depending on several "real roots".

=====
RealClosure examples
=====

```

The Real Closure 1.0 package provided by Renaud Rioboo consists of different packages, categories and domains :

The package RealPolynomialUtilitiesPackage which needs a Field F and a UnivariatePolynomialCategory domain with coefficients in F. It computes some simple functions such as Sturm and Sylvester sequences sturmSequence, sylvesterSequence.

The category RealRootCharacterizationCategory provides abstract functions to work with "real roots" of univariate polynomials. These resemble variables with some functionality needed to compute important operations.

The category RealClosedField provides common operations available over

real closed fields. These include finding all the roots of a univariate polynomial, taking square (and higher) roots, ...

The domain `RightOpenIntervalRootCharacterization` is the main code that provides the functionality of `RealRootCharacterizationCategory` for the case of archimedean fields. Abstract roots are encoded with a left closed right open interval containing the root together with a defining polynomial for the root.

The `RealClosure` domain is the end-user code. It provides usual arithmetic with real algebraic numbers, along with the functionality of a real closed field. It also provides functions to approximate a real algebraic number by an element of the base field. This approximation may either be absolute, approximate or relative (`relativeApprox`).

=====
CAVEATS
=====

Since real algebraic expressions are stored as depending on "real roots" which are managed like variables, there is an ordering on these. This ordering is dynamical in the sense that any new algebraic takes precedence over older ones. In particular every creation function raises a new "real root". This has the effect that when you type something like `sqrt(2) + sqrt(2)` you have two new variables which happen to be equal. To avoid this name the expression such as in `s2 := sqrt(2) ; s2 + s2`

Also note that computing times depend strongly on the ordering you implicitly provide. Please provide algebraics in the order which seems most natural to you.

=====
LIMITATIONS
=====

This packages uses algorithms which are published in [1] and [2] which are based on field arithmetics, in particular for polynomial gcd related algorithms. This can be quite slow for high degree polynomials and subresultants methods usually work best. Beta versions of the package try to use these techniques in a better way and work significantly faster. These are mostly based on unpublished algorithms and cannot be distributed. Please contact the author if you have a particular problem to solve or want to use these versions.

Be aware that approximations behave as post-processing and that all computations are done exactly. They can thus be quite time consuming when depending on several 'real roots'.

```

EXAMPLES

```
=====
```

We shall work with the real closure of the ordered field of rational numbers.

```
Ran := RECLOS(FRAC INT)
RealClosure Fraction Integer
Type: Domain
```

Some simple signs for square roots, these correspond to an extension of degree 16 of the rational numbers. Examples provided by J. Abbot.

```
fourSquares(a:Ran,b:Ran,c:Ran,d:Ran):Ran==sqrt(a)+sqrt(b)-sqrt(c)-sqrt(d)
Type: Void
```

These produce values very close to zero.

```
squareDiff1 := fourSquares(73,548,60,586)
+---+ +---+ +---+ +---+
- \|586 - \|60 + \|548 + \|73
Type: RealClosure Fraction Integer

recip(squareDiff1)
+---+ +---+ +---+ +---+ +---+
((54602\|548 + 149602\|73)\|60 + 49502\|73 \|548 + 9900895)\|586
+
+---+ +---+ +---+ +---+ +---+
(154702\|73 \|548 + 30941947)\|60 + 10238421\|548 + 28051871\|73
Type: Union(RealClosure Fraction Integer,...)

— domain RECLOS RealClosure —

```

)abbrev domain RECLOS RealClosure
++ Author: Renaud Rioboo
++ Date Created: summer 1988
++ Date Last Updated: January 2004
++ Description:
++ This domain implements the real closure of an ordered field.
++ Note:
++ The code here is generic i.e. it does not depend of the way the operations

```

```

++ are done. The two macros PME and SEG should be passed as functorial
++ arguments to the domain. It does not help much to write a category
++ since non trivial methods cannot be placed there either.
++

```

```

## — domain RGCHAIN RegularChain —

```

)abbrev domain RGCHAIN RegularChain
++ Author: Marc Moreno Maza
++ Date Created: 01/1999
++ Date Last Updated: 23/01/1999
++ Description:
++ A domain for regular chains (i.e. regular triangular sets) over
++ a Gcd-Domain and with a fix list of variables.
++ This is just a front-end for the \spadtype{RegularTriangularSet}
++ domain constructor.

RegularChain(R,ls): Exports == Implementation where
 R : GcdDomain
 ls: List Symbol
 V ==> OrderedVariableList ls
 E ==> IndexedExponents V
 P ==> NewSparseMultivariatePolynomial(R,V)
 TS ==> RegularTriangularSet(R,E,V,P)

Exports == RegularTriangularSetCategory(R,E,V,P) with
 zeroSetSplit: (List P, Boolean, Boolean) -> List $
 ++ \spad{zeroSetSplit(lp,clos?,info?)} returns a list \spad{lhs} of
 ++ regular chains such that the union of the closures of their regular
 ++ zero sets equals the affine variety associated with \spad{lp}.
 ++ Moreover, if \spad{clos?} is \spad{false} then the union of the
 ++ regular zero set of the \spad{ts} (for \spad{ts} in \spad{lhs})
 ++ equals this variety.
 ++ If \spad{info?} is \spad{true} then some information is
 ++ displayed during the computations. See
 ++ zeroSetSplit from RegularTriangularSet.

Implementation == RegularTriangularSet(R,E,V,P)

=====
RegularTriangularSet examples
=====

```

The RegularTriangularSet domain constructor implements regular triangular sets. These particular triangular sets were introduced by M. Kalkbrener (1991) in his PhD Thesis under the name regular chains. Regular chains and their related concepts are presented in the paper "On the Theories of Triangular sets" By P. Aubry, D. Lazard and M. Moreno Maza (to appear in the Journal of Symbolic Computation). The RegularTriangularSet constructor also provides a new method (by the third author) for solving polynomial system by means of regular chains. This method has two ways of solving. One has the same specifications as Kalkbrener's algorithm (1991) and the other is closer to Lazard's method (Discr. App. Math, 1991). Moreover, this new method removes redundant component from the decompositions when this is not too expensive. This is always the case with square-free regular chains. So if you want to obtain decompositions without redundant components just use the SquareFreeRegularTriangularSet domain constructor or the LazardSetSolvingPackage package constructor. See also the LexTriangularPackage and ZeroDimensionalSolvePackage for the case of algebraic systems with a finite number of (complex) solutions.

One of the main features of regular triangular sets is that they naturally define towers of simple extensions of a field. This allows to perform with multivariate polynomials the same kind of operations as one can do in an EuclideanDomain.

The RegularTriangularSet constructor takes four arguments. The first one, R, is the coefficient ring of the polynomials; it must belong to the category GcdDomain. The second one, E, is the exponent monoid of the polynomials; it must belong to the category OrderedAbelianMonoidSup. The third one, V, is the ordered set of variables; it must belong to the category OrderedSet. The last one is the polynomial ring; it must belong

to the category `RecursivePolynomialCategory(R,E,V)`. The abbreviation for `RegularTriangularSet` is `REGSET`. See also the constructor `RegularChain` which only takes two arguments, the coefficient ring and the ordered set of variables; in that case, polynomials are necessarily built with the `NewSparseMultivariatePolynomial` domain constructor.

We shall explain now how to use the constructor `REGSET` and how to read the decomposition of a polynomial system by means of regular sets.

Let us give some examples. We start with an easy one (Donati-Traverso) in order to understand the two ways of solving polynomial systems provided by the `REGSET` constructor.

Define the coefficient ring.

```
R := Integer
Integer
Type: Domain
```

Define the list of variables,

```
ls : List Symbol := [x,y,z,t]
[x,y,z,t]
Type: List Symbol
```

and make it an ordered set;

```
V := OVAR(ls)
OrderedVariableList [x,y,z,t]
Type: Domain
```

then define the exponent monoid.

```
E := IndexedExponents V
IndexedExponents OrderedVariableList [x,y,z,t]
Type: Domain
```

Define the polynomial ring.

```
P := NSMP(R, V)
NewSparseMultivariatePolynomial(Integer,OrderedVariableList [x,y,z,t])
Type: Domain
```

Let the variables be polynomial.

```
x: P := 'x
x
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])
y: P := 'y
```

```

y
 Type: NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t])

z: P := 'z
z
 Type: NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t])

t: P := 't
t
 Type: NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t])

```

Now call the RegularTriangularSet domain constructor.

```

T := REGSET(R,E,V,P)
RegularTriangularSet(Integer,IndexedExponents OrderedVariableList [x,y,z,t],0
rderedVariableList [x,y,z,t],NewSparseMultivariatePolynomial(Integer,OrderedV
ariableList [x,y,z,t]))
 Type: Domain

```

Define a polynomial system.

```

p1 := x ** 31 - x ** 6 - x - y
 31 6
 x - x - x - y
 Type: NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t])

p2 := x ** 8 - z
 8
 x - z
 Type: NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t])

p3 := x ** 10 - t
 10
 x - t
 Type: NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t])

lp := [p1, p2, p3]
 31 6 8 10
 [x - x - x - y, x - z, x - t]
 Type: List NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t])

```

First of all, let us solve this system in the sense of Kalkbrener.

```

zeroSetSplit(lp)$T
 5 4 2 3 8 5 3 2 4 2
 [{z - t ,t z y + 2z y - t + 2t + t - t ,(t - t)x - t y - z}]
 Type: List RegularTriangularSet(Integer,
 IndexedExponents OrderedVariableList [x,y,z,t],
 OrderedVariableList [x,y,z,t],
 NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t]))

```

And now in the sense of Lazard (or Wu and other authors).

```

lts := zeroSetSplit(lp,false)$T
 5 4 2 3 8 5 3 2 4 2
 [{z - t ,t z y + 2z y - t + 2t + t - t ,(t - t)x - t y - z },
 3 5 2 3 2
 {t - 1,z - t,t z y + 2z y + 1,z x - t}, {t,z,y,x}]
 Type: List RegularTriangularSet(Integer,
 IndexedExponents OrderedVariableList [x,y,z,t],
 OrderedVariableList [x,y,z,t],
 NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t]))

```

We can see that the first decomposition is a subset of the second.  
So how can both be correct ?

Recall first that polynomials from a domain of the category  
RecursivePolynomialCategory are regarded as univariate polynomials in  
their main variable. For instance the second polynomial in the first  
set of each decomposition has main variable  $y$  and its initial  
(i.e. its leading coefficient w.r.t. its main variable) is  $t z$ .

Now let us explain how to read the second decomposition. Note that  
the non-constant initials of the first set are  $t^4-t$  and  $t z$ . Then  
the solutions described by this first set are the common zeros of  
its polynomials that do not cancel the polynomials  $t^4-t$  and  $t y z$ .  
Now the solutions of the input system  $lp$  satisfying these equations  
are described by the second and the third sets of the decomposition.  
Thus, in some sense, they can be considered as degenerated solutions.  
The solutions given by the first set are called the generic points of  
the system; they give the general form of the solutions. The first  
decomposition only provides these generic points. This latter  
decomposition is useful when they are many degenerated solutions  
(which is sometimes hard to compute) and when one is only interested  
in general informations, like the dimension of the input system.

We can get the dimensions of each component of a decomposition as follows.

```

[coHeight(ts) for ts in lts]
[1,0,0]
 Type: List NonNegativeInteger

```

Thus the first set has dimension one. Indeed  $t$  can take any value, except 0 or any third root of 1, whereas  $z$  is completely determined from  $t$ ,  $y$  is given by  $z$  and  $t$ , and finally  $x$  is given by the other three variables. In the second and the third sets of the second decomposition the four variables are completely determined and thus these sets have dimension zero.

We give now the precise specifications of each decomposition. This assume some mathematical knowledge. However, for the non-expert user, the above explanations will be sufficient to understand the other features of the RSEGSET constructor.

The input system  $lp$  is decomposed in the sense of Kalkbrener as finitely many regular sets  $T_1, \dots, T_s$  such that the radical ideal generated by  $lp$  is the intersection of the radicals of the saturated ideals of  $T_1, \dots, T_s$ . In other words, the affine variety associated with  $lp$  is the union of the closures (w.r.t. Zarisky topology) of the regular-zeros sets of  $T_1, \dots, T_s$ .

N. B. The prime ideals associated with the radical of the saturated ideal of a regular triangular set have all the same dimension; moreover these prime ideals can be given by characteristic sets with the same main variables. Thus a decomposition in the sense of Kalkbrener is unmixed dimensional. Then it can be viewed as a lazy decomposition into prime ideals (some of these prime ideals being merged into unmixed dimensional ideals).

Now we explain the other way of solving by means of regular triangular sets. The input system  $lp$  is decomposed in the sense of Lazard as finitely many regular triangular sets  $T_1, \dots, T_s$  such that the affine variety associated with  $lp$  is the union of the regular-zeros sets of  $T_1, \dots, T_s$ . Thus a decomposition in the sense of Lazard is also a decomposition in the sense of Kalkbrener; the converse is false as we have seen before.

When the input system has a finite number of solutions, both ways of solving provide similar decompositions as we shall see with this second example (Caprasse).

Define a polynomial system.

```
f1 := y**2*z+2*x*y*t-2*x-z
 2
(2t y - 2)x + z y - z
 Type: NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t])

f2:=-x**3*z+ 4*x*y**2*z+4*x**2*y*t+2*y**3*t+4*x**2-10*y**2+4*x*z-10*y*t+2
 3 2 2 3 2
```

```

- z x + (4t y + 4)x + (4z y + 4z)x + 2t y - 10y - 10t y + 2
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])

f3 := 2*y*z*t+x*t**2-x-2*z
2
(t - 1)x + 2t z y - 2z
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])

f4:=-x*z**3+4*y*z**2*t+4*x*z*t**2+2*y*t**3+4*x*z+4*z**2-10*y*t- 10*t**2+2
3 2 2 3 2 2
(- z + (4t + 4)z)x + (4t z + 2t - 10t)y + 4z - 10t + 2
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])

lf := [f1, f2, f3, f4]
2
[(2t y - 2)x + z y - z,
3 2 2 3 2
- z x + (4t y + 4)x + (4z y + 4z)x + 2t y - 10y - 10t y + 2,
2
(t - 1)x + 2t z y - 2z,
3 2 2 3 2 2
(- z + (4t + 4)z)x + (4t z + 2t - 10t)y + 4z - 10t + 2]
Type: List NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])

```

First of all, let us solve this system in the sense of Kalkbrener.

```

zeroSetSplit(lf)$T
2 8 6 2 3 2
[{t - 1,z - 16z + 256z - 256,t y - 1,(z - 8z)x - 8z + 16},
2 2 2
{3t + 1,z - 7t - 1,y + t,x + z},
8 6 2 3 2
{t - 10t + 10t - 1,z,(t - 5t)y - 5t + 1,x},
2 2
{t + 3,z - 4,y + t,x - z}]
Type: List RegularTriangularSet(Integer,
IndexedExponents OrderedVariableList [x,y,z,t],
OrderedVariableList [x,y,z,t],
NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t]))

```

And now in the sense of Lazard (or Wu and other authors).

```

lts2 := zeroSetSplit(lf,false)$T
8 6 2 3 2
[{t - 10t + 10t - 1,z,(t - 5t)y - 5t + 1,x},

```

```

 2 8 6 2 3 2
{t - 1,z - 16z + 256z - 256,t y - 1,(z - 8z)x - 8z + 16},
 2 2 2 2 2
{3t + 1,z - 7t - 1,y + t,x + z}, {t + 3,z - 4,y + t,x - z}]
Type: List RegularTriangularSet(Integer,
 IndexedExponents OrderedVariableList [x,y,z,t],
 OrderedVariableList [x,y,z,t],
 NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t]))

```

Up to the ordering of the components, both decompositions are identical.

Let us check that each component has a finite number of solutions.

```

[coHeight(ts) for ts in lts2]
[0,0,0,0]
Type: List NonNegativeInteger

```

Let us count the degrees of each component,

```

degrees := [degree(ts) for ts in lts2]
[8,16,4,4]
Type: List NonNegativeInteger

```

and compute their sum.

```

reduce(+,degrees)
32
Type: PositiveInteger

```

We study now the options of the zeroSetSplit operation. As we have seen yet, there is an optional second argument which is a boolean value. If this value is true (this is the default) then the decomposition is computed in the sense of Kalkbrener, otherwise it is computed in the sense of Lazard.

There is a second boolean optional argument that can be used (in that case the first optional argument must be present). This second option allows you to get some information during the computations.

Therefore, we need to understand a little what is going on during the computations. An important feature of the algorithm is that the intermediate computations are managed in some sense like the processes of a Unix system. Indeed, each intermediate computation may generate other intermediate computations and the management of all these computations is a crucial task for the efficiency. Thus any intermediate computation may be suspended, killed or resumed, depending on algebraic considerations that determine priorities for these processes. The goal is of course to go as fast as possible towards the final decomposition which means to avoid as much as possible unnecessary computations.

To follow the computations, one needs to set to true the second argument. Then a lot of numbers and letters are displayed. Between a [ and a ] one has the state of the processes at a given time. Just after [ one can see the number of processes. Then each process is represented by two numbers between < and >. A process consists of a list of polynomial ps and a triangular set ts; its goal is to compute the common zeros of ps that belong to the regular-zeros set of ts. After the processes, the number between pipes gives the total number of polynomials in all the sets ps. Finally, the number between braces gives the number of components of a decomposition that are already computed. This number may decrease.

Let us take a third example (Czapor-Geddes-Wang) to see how this information is displayed.

Define a polynomial system.

```

u : R := 2
 2
 Type: Integer

q1 := 2*(u-1)**2+ 2*(x-z*x+z**2)+ y**2*(x-1)**2- 2*u*x+ 2*y*t*(1-x)*(x-z)+_
 2*u*z*t*(t-y)+ u**2*t**2*(1-2*z)+ 2*u*t**2*(z-x)+ 2*u*t*y*(z-1)+_
 2*u*z*x*(y+1)+ (u**2-2*u)*z**2*t**2+ 2*u**2*z**2+ 4*u*(1-u)*z+_
 t**2*(z-x)**2}
 2 2 2 2 2 2 2 2

Between a sequence of processes, thus between a ] and a [ you can see capital letters W, G, I and lower case letters i, w. Each time a capital letter appears a non-trivial computation has be performed and its result is put in a hash-table. Each time a lower case letter appears a needed result has been found in an hash-table. The use of these hash-tables generally speed up the computations. However, on very large systems, it may happen that these hash-tables become too big to be handle by your AXIOM configuration. Then in these exceptional cases, you may prefer getting a result (even if it takes a long time) than getting nothing. Hence you need to know how to prevent the RSEGSET constructor from using these hash-tables. In that case you will be using the zeroSetSplit with five arguments. The first one is the input system lp as above. The second one is a boolean value hash? which is true iff you want to use hash-tables. The third one is boolean value clos? which is true iff you want to solve your system in the sense of Kalkbrener, the other way remaining that of Lazard. The fourth argument is boolean value info? which is true iff you want to display information during the computations. The last one is boolean value prep? which is true iff you want to use some heuristics that are performed on the input system before starting the

real algorithm. The value of this flag is true when you are using `zeroSetSplit` with less than five arguments. Note that there is no available signature for `zeroSetSplit` with four arguments.

We finish this section by some remarks about both ways of solving, in the sense of Kalkbrener or in the sense of Lazard. For problems with a finite number of solutions, there are theoretically equivalent and the resulting decompositions are identical, up to the ordering of the components. However, when solving in the sense of Lazard, the algorithm behaves differently. In that case, it becomes more incremental than in the sense of Kalkbrener. That means the polynomials of the input system are considered one after another whereas in the sense of Kalkbrener the input system is treated more globally.

This makes an important difference in positive dimension. Indeed when solving in the sense of Kalkbrener, the Primeidealkettensatz of Krull is used. That means any regular triangular containing more polynomials than the input system can be deleted. This is not possible when solving in the sense of Lazard. This explains why Kalkbrener's decompositions usually contain less components than those of Lazard. However, it may happen with some examples that the incremental process (that cannot be used when solving in the sense of Kalkbrener) provide a more efficient way of solving than the global one even if the Primeidealkettensatz is used. Thus just try both, with the various options, before concluding that you cannot solve your favorite system with `zeroSetSplit`. There exist more options at the development level that are not currently available in this public version.

## — domain REGSET RegularTriangularSet —

```

)abbrev domain REGSET RegularTriangularSet
++ Author: Marc Moreno Maza
++ Date Created: 08/25/1998
++ Date Last Updated: 16/12/1998
++ References :
++ [1] M. MORENO MAZA "A new algorithm for computing triangular
++ decomposition of algebraic varieties" NAG Tech. Rep. 4/98.
++ Description:
++ This domain provides an implementation of regular chains.
++ Moreover, the operation zeroSetSplit is an implementation of a new
++ algorithm for solving polynomial systems by means of regular chains.

RegularTriangularSet(R,E,V,P) : Exports == Implementation where

 R : GcdDomain
 E : OrderedAbelianMonoidSup
 V : OrderedSet
 P : RecursivePolynomialCategory(R,E,V)
 N ==> NonNegativeInteger
 Z ==> Integer

— RewriteRule.help —

=====  
RewriteRule examples  
=====

For example:

```
logrule := rule log(x) + log(y) == log(x*y)
 log(y) + log(x) + %C == log(x y) + %C
```

```
f := log(sin(x)) + log(x)
 log(sin(x)) + log(x)
```

```
logrule f
 log(x sin(x))
```

Note that you cannot write the simple form of a rule as:

```
rule1 := rule a*x+b == b*x+a
```

as this causes an infinite loop. The pattern is properly matched but the result also properly matches and the pattern is applied again.

++ Author: Manuel Bronstein
++ Date Created: 24 Oct 1988
++ Date Last Updated: 26 October 1993
++ Description:
++ Rules for the pattern matcher

RewriteRule(Base, R, F): Exports == Implementation where
 Base : SetCategory
 R : Join(Ring, PatternMatchable Base, OrderedSet,
 ConvertibleTo Pattern Base)
 F : Join(FunctionSpace R, PatternMatchable Base,
 ConvertibleTo Pattern Base)

P ==> Pattern Base

Exports ==>
 Join(SetCategory, Eltable(F, F), RetractableTo Equation F) with
 rule : (F, F) -> $
 ++ rule(f, g) creates the rewrite rule: \spad{f == eval(g, g is f)},
 ++ with left-hand side f and right-hand side g.
 ++
 ++X logrule := rule log(x) + log(y) == log(x*y)
 ++X f := log(sin(x)) + log(x)
 ++X logrule f
 rule : (F, F, List Symbol) -> $

```

```

++ rule(f, g, [f1,...,fn]) creates the rewrite rule
++ \spad{f == eval(eval(g, g is f), [f1,...,fn])},
++ that is a rule with left-hand side f and right-hand side g;
++ The symbols f1,...,fn are the operators that are considered
++ quoted, that is they are not evaluated during any rewrite,
++ but just applied formally to their arguments.
suchThat: ($, List Symbol, List F -> Boolean) -> $
++ suchThat(r, [a1,...,an], f) returns the rewrite rule r with
++ the predicate \spad{f(a1,...,an)} attached to it.
pattern : $ -> P
++ pattern(r) returns the pattern corresponding to
++ the left hand side of the rule r.
lhs : $ -> F
++ lhs(r) returns the left hand side of the rule r.
rhs : $ -> F
++ rhs(r) returns the right hand side of the rule r.
elt : ($, F, PositiveInteger) -> F
++ elt(r,f,n) or r(f, n) applies the rule r to f at most n times.
quotedOperators: $ -> List Symbol
++ quotedOperators(r) returns the list of operators
++ on the right hand side of r that are considered
++ quoted, that is they are not evaluated during any rewrite,
++ but just applied formally to their arguments.

## domain ROIRC RightOpenIntervalRootCharacterization

The domain RightOpenIntervalRootCharacterization is the main code that provides the functionalities of RealRootCharacterizationCategory for the case of archimedean fields. Abstract roots are encoded with a left closed right open interval containing the root together with a defining polynomial for the root.

### CAVEATS

Since real algebraic expressions are stored as depending on "real roots" which are managed like variables, there is an ordering on these. This ordering is dynamical in the sense that any new algebraic takes precedence over older ones. In particular every creation function raises a new "real root". This has the effect that when you type something like  $\sqrt{2} + \sqrt{2}$  you have two new variables which happen to be equal. To avoid this name the expression such as in  $s2 := \sqrt{2}; s2 + s2$

Also note that computing times depend strongly on the ordering you implicitly provide. Please provide algebraics in the order which most natural to you.

### LIMITATIONS

The file reclos.input show some basic use of the package. This packages uses algorithms which are published in [1] and [2] which are based on field arithmetics, in particular for polynomial gcd related algorithms. This can be quite slow for high degree polynomials and subresultants methods usually work best. Beta versions of the package try to use these techniques in a better way and work significantly faster. These are mostly based on unpublished algorithms and cannot be distributed. Please contact the author if you have a particular problem to solve or want to use these versions.

Be aware that approximations behave as post-processing and that all computations are done exactly. They can thus be quite time consuming when depending on several "real roots".

RomanNumeral Examples

---

The Roman numeral package was added to Axiom in MCMLXXXVI for use in denoting higher order derivatives.

For example, let  $f$  be a symbolic operator.

```
f := operator 'f
f
```

Type: BasicOperator

This is the seventh derivative of f with respect to x.

```
D(f x,x,7)
(vii)
f (x)
```

Type: Expression Integer

You can have integers printed as Roman numerals by declaring variables to be of type RomanNumeral (abbreviation ROMAN).

```
a := roman(1978 - 1965)
XIII
```

Type: RomanNumeral

This package now has a small but devoted group of followers that claim this domain has shown its efficacy in many other contexts. They claim that Roman numerals are every bit as useful as ordinary integers.

In a sense, they are correct, because Roman numerals form a ring and you can therefore construct polynomials with Roman numeral coefficients, matrices over Roman numerals, etc..

```
x : UTS(ROMAN,'x,0) := x
x
```

Type: UnivariateTaylorSeries(RomanNumeral,x,0)

Was Fibonacci Italian or ROMAN?

```
recip(1 - x - x**2)
 2 3 4 5 6 7 8
I + x + II x + III x + V x + VIII x + XIII x + XXI x + XXXIV x
+
 9 10 11
LV x + LXXXIX x + O(x)
```

Type: Union(UnivariateTaylorSeries(RomanNumeral,x,0),...)

You can also construct fractions with Roman numeral numerators and denominators, as this matrix Hilberticus illustrates.

```
m : MATRIX FRAC ROMAN
```

Type: Void

```
m := matrix [[1/(i + j) for i in 1..3] for j in 1..3]
+ I I I+
|-- --- --|
|II III IV|
```

```

| |
| I I I |
|--- -- - |
|III IV V |
| |
| I I I |
|--- - --|
+IV V VI+

```

Type: Matrix Fraction RomanNumeral

Note that the inverse of the matrix has integral ROMAN entries.

```

inverse m
+LXXII - CCXL CLXXX +
| |
|- CCXL CM - DCCXX|
| |
+CLXXX - DCCXX DC +
Type: Union(Matrix Fraction RomanNumeral,...)

```

Unfortunately, the spoiler-sports say that the fun stops when the numbers get big---mostly because the Romans didn't establish conventions about representing very large numbers.

```

y := factorial 10
3628800
Type: PositiveInteger

```

You work it out!

```

roman y
((((I))))(((I))))(((I)))) ((I))((I))((I))((I))((I))((I))((I)) ((I))(
(I) MMMMMMMDCCC
Type: RomanNumeral

```

Issue the system command `)show RomanNumeral` to display the full list of operations defined by RomanNumeral.

```

a := roman(78)
LXXVIII
Type: RomanNumeral

```

```

b := roman(87)
LXXXVII
Type: RomanNumeral

```

```

a + b
CLXV
Type: RomanNumeral

```

```
a * b
MMMMMDCCLXXXVI
Type: RomanNumeral
```

```
b rem a
IX
Type: RomanNumeral
```

— domain **ROUTINE** RoutinesTable —

```

)abbrev domain ROUTINE RoutinesTable
++ Author: Brian Dupee
++ Date Created: August 1994
++ Date Last Updated: December 1997
++ Description:
++ \axiomType{RoutinesTable} implements a database and associated tuning
++ mechanisms for a set of known NAG routines

```

```

RoutinesTable(): E == I where
 F ==> Float
 ST ==> String
 LST ==> List String
 Rec ==> Record(key:Symbol,entry:Any)
 RList ==> List(Record(key:Symbol,entry:Any))
 IFL ==> List(Record(ifeil:Integer,instruction:ST))
 Entry ==> Record(chapter:ST, type:ST, domainName: ST,
 defaultMin:F, measure:F, failList:IFL, explList:LST)

E ==> TableAggregate(Symbol,Any) with

concat:(%,%) -> %
 ++ concat(x,y) merges two tables x and y
routines:() -> %
 ++ routines() initialises a database of known NAG routines
selectIntegrationRoutines:% -> %
 ++ selectIntegrationRoutines(R) chooses only those routines from
 ++ the database which are for integration
selectOptimizationRoutines:% -> %
 ++ selectOptimizationRoutines(R) chooses only those routines from
 ++ the database which are for integration
selectPDERoutines:% -> %
 ++ selectPDERoutines(R) chooses only those routines from the
 ++ database which are for the solution of PDE's
selectODEIVPRoutines:% -> %
 ++ selectODEIVPRoutines(R) chooses only those routines from the
 ++ database which are for the solution of ODE's
selectFiniteRoutines:% -> %
 ++ selectFiniteRoutines(R) chooses only those routines from the
 ++ database which are designed for use with finite expressions
selectSumOfSquaresRoutines:% -> %
 ++ selectSumOfSquaresRoutines(R) chooses only those routines from the
 ++ database which are designed for use with sums of squares
selectNonFiniteRoutines:% -> %
 ++ selectNonFiniteRoutines(R) chooses only those routines from the
 ++ database which are designed for use with non-finite expressions.
selectMultiDimensionalRoutines:% -> %
 ++ selectMultiDimensionalRoutines(R) chooses only those routines from
 ++ the database which are designed for use with multi-dimensional
 ++ expressions
changeThreshold:(%,Symbol,F) -> %
 ++ changeThreshold(R,s,newValue) changes the value below which,
 ++ given a NAG routine generating a higher measure, the routines will
 ++ make no attempt to generate a measure.
changeMeasure:(%,Symbol,F) -> %
 ++ changeMeasure(R,s,newValue) changes the maximum value for a
 ++ measure of the given NAG routine.
getMeasure:(%,Symbol) -> F
 ++ getMeasure(R,s) gets the current value of the maximum measure for

```

```

 ++ the given NAG routine.
 getExplanations:(%,ST) -> LST
 ++ getExplanations(R,s) gets the explanations of the output parameters for
 ++ the given NAG routine.
 deleteRoutine!:(%,Symbol) -> %
 ++ deleteRoutine!(R,s) destructively deletes the given routine from
 ++ the current database of NAG routines
 showTheRoutinesTable:() -> %
 ++ showTheRoutinesTable() returns the current table of NAG routines.
 recoverAfterFail:(%,ST,Integer) -> Union(ST,"failed")
 ++ recoverAfterFail(routs,routineName,ifailValue) acts on the
 ++ instructions given by the ifail list
 finiteAggregate

=====
ScriptFormulaFormat examples
=====
```

ScriptFormulaFormat provides a coercion from OutputForm} to IBM SCRIPT/VS Mathematical Formula Format. The basic SCRIPT formula format object consists of three parts: a prologue, a formula part and an epilogue. The functions prologue, formula and epilogue extract these parts, respectively. The central parts of the expression go into the formula part. The other parts can be set (setPrologue!, setEpilogue!) so that contain the appropriate tags for printing. For example, the prologue and epilogue might simply contain ":df." and ":edf." so that the formula section will be printed in display math mode.

)abbrev domain FORMULA ScriptFormulaFormat
++ Author: Robert S. Sutor
++ Date Created: 1987 through 1990
++ References:
++ SCRIPT Mathematical Formula Formatter User's Guide, SH20-6453,
++ IBM Corporation, Publishing Systems Information Development,
++ Dept. G68, P.O. Box 1900, Boulder, Colorado, USA 80301-9191.
++ Description:
++ \spadtype{ScriptFormulaFormat} provides a coercion from
++ \spadtype{OutputForm} to IBM SCRIPT/VS Mathematical Formula Format.
++ The basic SCRIPT formula format object consists of three parts: a
++ prologue, a formula part and an epilogue. The functions
++ \spadfun{prologue}, \spadfun{formula} and \spadfun{epilogue}
++ extract these parts, respectively. The central parts of the expression
++ go into the formula part. The other parts can be set
++ (\spadfun{setPrologue!}, \spadfun{setEpilogue!}) so that contain the
++ appropriate tags for printing. For example, the prologue and
++ epilogue might simply contain ":df." and ":edf." so that the
++ formula section will be printed in display math mode.

ScriptFormulaFormat(): public == private where
E ==> OutputForm
I ==> Integer
L ==> List
S ==> String

public == SetCategory with
coerce: E -> %
++ coerce(o) changes o in the standard output format to
++ SCRIPT formula format.
convert: (E,I) -> %
++ convert(o,step) changes o in standard output format to
++ SCRIPT formula format and also adds the given step number.
++ This is useful if you want to create equations with given numbers
++ or have the equation numbers correspond to the interpreter step
++ numbers.
display: (% , I) -> Void
++ display(t,width) outputs the formatted code t so that each
++ line has length less than or equal to \spadvar{width}.
display: % -> Void
++ display(t) outputs the formatted code t so that each
++ line has length less than or equal to the value set by
++ the system command \spadsyscom{set output length}.
epilogue: % -> L S
++ epilogue(t) extracts the epilogue section of a formatted object t.
formula: % -> L S
++ formula(t) extracts the formula section of a formatted object t.

```

```

new: () -> %
 ++ new() create a new, empty object. Use \spadfun{setPrologue!},
 ++ \spadfun{setFormula!} and \spadfun{setEpilogue!} to set the
 ++ various components of this object.
prologue: % -> L S
 ++ prologue(t) extracts the prologue section of a formatted object t.
setEpilogue!: (% , L S) -> L S
 ++ setEpilogue!(t,strings) sets the epilogue section of a
 ++ formatted object t to strings.
setFormula!: (% , L S) -> L S
 ++ setFormula!(t,strings) sets the formula section of a
 ++ formatted object t to strings.
setPrologue!: (% , L S) -> L S
 ++ setPrologue!(t,strings) sets the prologue section of a
 ++ formatted object t to strings.

— Segment.help —

```
=====
Segment examples
=====
```

The Segment domain provides a generalized interval type.

Segments are created using the .. construct by indicating the (included) end points.

```
s := 3..10
 3..10
 Type: Segment PositiveInteger
```

The first end point is called the lo and the second is called hi.

```
lo s
 3
 Type: PositiveInteger
```

These names are used even though the end points might belong to an unordered set.

```
hi s
 10
 Type: PositiveInteger
```

In addition to the end points, each segment has an integer "increment". An increment can be specified using the "by" construct.

```
t := 10..3 by -2
 10..3 by - 2
 Type: Segment PositiveInteger
```

This part can be obtained using the incr function.

```
incr s
 1
 Type: PositiveInteger
```

Unless otherwise specified, the increment is 1.

```
incr t
 - 2
```

Type: Integer

A single value can be converted to a segment with equal end points. This happens if segments and single values are mixed in a list.

```
l := [1..3, 5, 9, 15..11 by -1]
 [1..3,5..5,9..9,15..11 by - 1]
```

Type: List Segment PositiveInteger

If the underlying type is an ordered ring, it is possible to perform additional operations. The `expand` operation creates a list of points in a segment.

```
expand s
 [3,4,5,6,7,8,9,10]
```

Type: List Integer

If  $k > 0$ , then `expand(l..h by k)` creates the list  $[l, l+k, \dots, lN]$  where  $lN \leq h < lN+k$ . If  $k < 0$ , then  $lN \geq h > lN+k$ .

```
expand t
 [10,8,6,4]
```

Type: List Integer

It is also possible to expand a list of segments. This is equivalent to appending lists obtained by expanding each segment individually.

```
expand l
 [1,2,3,5,9,15,14,13,12,11]
```

Type: List Integer

=====
SegmentBinding examples
=====
```

The SegmentBinding type is used to indicate a range for a named symbol.

First give the symbol, then an = and finally a segment of values.

```
x = a..b
x= a..b
```

Type: SegmentBinding Symbol

This is used to provide a convenient syntax for arguments to certain operations.

```
sum(i**2, i = 0..n)
 3 2
 2n + 3n + n

 6
```

Type: Fraction Polynomial Integer

```
draw(x**2, x = -2..2)
TwoDimensionalViewport: "x*x"
Type: TwoDimensionalViewport
```

The left-hand side must be of type Symbol but the right-hand side can be a segment over any type.

```
sb := y = 1/2..3/2
 1 3
y= (-)..(-)
 2 2
```

Type: SegmentBinding Fraction Integer

The left- and right-hand sides can be obtained using the variable and segment operations.

```
variable(sb)
y
```

Type: Symbol

```
segment(sb)
 1 3
(-)..(-)
 2 2
```

Type: Segment Fraction Integer

)abbrev domain SEGBIND SegmentBinding
++ Author: Mark Botch
++ Date Last Updated: June 4, 1991
++ Description:
++ This domain is used to provide the function argument syntax \spad{v=a..b}.
++ This is used, for example, by the top-level \spadfun{draw} functions.

```

```

SegmentBinding(S:Type): Type with
 equation: (Symbol, Segment S) -> %
 ++ equation(v,a..b) creates a segment binding value with variable
 ++ \spad{v} and segment \spad{a..b}. Note that the interpreter parses
 ++ \spad{v=a..b} to this form.
 variable: % -> Symbol
 ++ variable(segb) returns the variable from the left hand side of
 ++ the \spadtype{SegmentBinding}. For example, if \spad{segb} is
 ++ \spad{v=a..b}, then \spad{variable(segb)} returns \spad{v}.
 segment : % -> Segment S
 ++ segment(segb) returns the segment from the right hand side of
 ++ the \spadtype{SegmentBinding}. For example, if \spad{segb} is
 ++ \spad{v=a..b}, then \spad{segment(segb)} returns \spad{a..b}.

if S has SetCategory then SetCategory

**— Set.help —**

=====  
Set examples  
=====

The Set domain allows one to represent explicit finite sets of values. These are similar to lists, but duplicate elements are not allowed.

Sets can be created by giving a fixed set of values ...

```

s := set [x**2-1, y**2-1, z**2-1]
 2 2 2
 {x - 1,y - 1,z - 1}
Type: Set Polynomial Integer

```

or by using a collect form, just as for lists. In either case, the set is formed from a finite collection of values.

```

t := set [x**i - i+1 for i in 2..10 | prime? i]
 2 3 5 7
 {x - 1,x - 2,x - 4,x - 6}
Type: Set Polynomial Integer

```

The basic operations on sets are `intersect`, `union`, `difference`, and `symmetricDifference`.

```
i := intersect(s,t)
 2
{x - 1}
 Type: Set Polynomial Integer
```

```
u := union(s,t)
 2 3 5 7 2 2
{x - 1,x - 2,x - 4,x - 6,y - 1,z - 1}
 Type: Set Polynomial Integer
```

The set `difference(s,t)` contains those members of `s` which are not in `t`.

```
difference(s,t)
 2 2
{y - 1,z - 1}
 Type: Set Polynomial Integer
```

The set `symmetricDifference(s,t)` contains those elements which are in `s` or `t` but not in both.

```
symmetricDifference(s,t)
 3 5 7 2 2
{x - 2,x - 4,x - 6,y - 1,z - 1}
 Type: Set Polynomial Integer
```

Set membership is tested using the `member?` operation.

```
member?(y, s)
false
 Type: Boolean
```

```
member?((y+1)*(y-1), s)
true
 Type: Boolean
```

The `subset?` function determines whether one set is a subset of another.

```
subset?(i, s)
true
 Type: Boolean
```

```
subset?(u, s)
false
 Type: Boolean
```

When the base type is finite, the absolute complement of a set is defined. This finds the set of all multiplicative generators of

PrimeField 11---the integers mod 11.

```
gs := set [g for i in 1..11 | primitive?(g := i::PF 11)]
 {2,6,7,8}
 Type: Set PrimeField 11
```

The following values are not generators.

```
complement gs
 {1,3,4,5,9,10,0}
 Type: Set PrimeField 11
```

Often the members of a set are computed individually; in addition, values can be inserted or removed from a set over the course of a computation.

There are two ways to do this:

```
a := set [i**2 for i in 1..5]
 {1,4,9,16,25}
 Type: Set PositiveInteger
```

One is to view a set as a data structure and to apply updating operations.

```
insert!(32, a)
 {1,4,9,16,25,32}
 Type: Set PositiveInteger

remove!(25, a)
 {1,4,9,16,32}
 Type: Set PositiveInteger

a
 {1,4,9,16,32}
 Type: Set PositiveInteger
```

The other way is to view a set as a mathematical entity and to create new sets from old.

```
b := b0 := set [i**2 for i in 1..5]
 {1,4,9,16,25}
 Type: Set PositiveInteger

b := union(b, {32})
 {1,4,9,16,25,32}
 Type: Set PositiveInteger

b := difference(b, {25})
 {1,4,9,16,32}
 Type: Set PositiveInteger
```

```
b0
 {1,4,9,16,25}
```

```
Type: Set PositiveInteger
```

— domain SET Set —

```
)abbrev domain SET Set
```

```
++ Author: Michael Monagan; revised by Richard Jenks
```

```
++ Date Created: August 87 through August 88
```

```
++ Date Last Updated: May 1991
```

```
++ Description:
```

```

++ A set over a domain D models the usual mathematical notion of a finite set
++ of elements from D.
++ Sets are unordered collections of distinct elements
++ (that is, order and duplication does not matter).
++ The notation \spad{set [a,b,c]} can be used to create
++ a set and the usual operations such as union and intersection are available
++ to form new sets.
++ In our implementation, \Language{} maintains the entries in
++ sorted order. Specifically, the parts function returns the entries
++ as a list in ascending order and
++ the extract operation returns the maximum entry.
++ Given two sets s and t where \spad{#s = m} and \spad{#t = n},
++ the complexity of\br
++ \tab{5}\spad{s = t} is \spad{0(\min(n,m))}\br
++ \tab{5}\spad{s < t} is \spad{0(\max(n,m))}\br
++ \tab{5}\spad{\union(s,t)}, \spad{\intersect(s,t)}, \spad{\minus(s,t)},\br
++ \tab{10} \spad{\symmetricDifference(s,t)} is \spad{0(\max(n,m))}\br
++ \tab{5}\spad{\member(x,t)} is \spad{0(n \log n)}\br
++ \tab{5}\spad{\insert(x,t)} and \spad{\remove(x,t)} is \spad{0(n)}

)abbrev domain SETMN SetOfMIntegersInOneToN
++ Author: Manuel Bronstein
++ Date Created: 10 January 1994
++ Date Last Updated: 10 January 1994
++ Description:
++ \spadtype{SetOfMIntegersInOneToN} implements the subsets of M integers
++ in the interval \spad{[1..n]}

SetOfMIntegersInOneToN(m, n): Exports == Implementation where
 PI ==> PositiveInteger
 N ==> NonNegativeInteger
 U ==> Union(%, "failed")
 n,m: PI

Exports ==> Finite with
 incrementKthElement: (%, PI) -> U
 ++ incrementKthElement(S,k) increments the k^{th} element of S,
 ++ and returns "failed" if the result is not a set of M integers
 ++ in \spad{1..n} any more.
 replaceKthElement: (%, PI, PI) -> U
 ++ replaceKthElement(S,k,p) replaces the k^{th} element of S by p,
 ++ and returns "failed" if the result is not a set of M integers
 ++ in \spad{1..n} any more.
 elements: % -> List PI
 ++ elements(S) returns the list of the elements of S in increasing order.
 setOfMinN: List PI -> %
 ++ setOfMinN([a_1,...,a_m]) returns the set {a_1,...,a_m}.

```

```

 ++ Error if {a_1,...,a_m} is not a set of M integers in \spad{1..n}.
enumerate: () -> Vector %
 ++ enumerate() returns a vector of all the sets of M integers in
 ++ \spad{1..n}.
member?: (PI, %) -> Boolean
 ++ member?(p, s) returns true is p is in s, false otherwise.
delta: (% , PI, PI) -> N
 ++ delta(S,k,p) returns the number of elements of S which are strictly
 ++ between p and the kth element of S.

=====
SequentialDifferentialVariable examples
=====

```

OrderlyDifferentialVariable adds a commonly used sequential ranking to the set of derivatives of an ordered list of differential indeterminates. A sequential ranking is a ranking  $<$  of the derivatives with the property that for any derivative  $v$ , there are only a finite number of derivatives  $u$  with  $u < v$ . This domain belongs to DifferentialVariableCategory. It defines weight to be just order, and it defines a sequential ranking  $<$  on derivatives  $u$  by the lexicographic order on the pair  $(\text{variable}(u), \text{order}(u))$ .

=====
SimpleAlgebraicExtension examples
=====
```

Algebraic extension of a ring by a single polynomial. Domain which represents simple algebraic extensions of arbitrary rings. The first argument to the domain, R, is the underlying ring, the second argument is a domain of univariate polynomials over K, while the last argument specifies the defining minimal polynomial.

The elements of the domain are canonically represented as polynomials of degree less than that of the minimal polynomial with coefficients in R. The second argument is both the type of the third argument and the underlying representation used by SAE itself.

— domain SAE SimpleAlgebraicExtension —

```

)abbrev domain SAE SimpleAlgebraicExtension
++ Author: Barry Trager, Manuel Bronstein, Clifton Williamson
++ Date Created: 1986
++ Date Last Updated: 9 May 1994
++ Description:
++ Algebraic extension of a ring by a single polynomial.
++ Domain which represents simple algebraic extensions of arbitrary
++ rings. The first argument to the domain, R, is the underlying ring,
++ the second argument is a domain of univariate polynomials over K,
++ while the last argument specifies the defining minimal polynomial.
++ The elements of the domain are canonically represented as polynomials
++ of degree less than that of the minimal polynomial with coefficients
++ in R. The second argument is both the type of the third argument and
++ the underlying representation used by \spadtype{SAE} itself.

## domain SINT SingleInteger

This type represents finite (machine) precision integers which wrap around at a machine dependent value. However, **SingleInteger** has type **EntireRing** which should have no non-zero divisors. But

$$(2 * 16 : SINT) * 2 = 0$$

on a 32 bit machine. Using **SingleInteger** is a pragmatic efficiency choice. In this condition, Axiom will complain that the result is not of type FIXNUM, which is the Common Lisp type for machine integers.

=====
SingleInteger examples
=====

```

The SingleInteger domain is intended to provide support in Axiom for machine integer arithmetic. It is generally much faster than (bignum) Integer arithmetic but suffers from a limited range of values. Since Axiom can be implemented on top of various dialects of Lisp, the actual representation of small integers may not correspond exactly to the host machines integer representation.

You can discover the minimum and maximum values in your implementation by using min and max.

```

min()$SingleInteger
- 2147483648
 Type: SingleInteger

```

```

max()$SingleInteger
2147483647
 Type: SingleInteger

```

To avoid confusion with Integer, which is the default type for integers, you usually need to work with declared variables.

```

a := 1234 :: SingleInteger
1234
 Type: SingleInteger

```

or use package calling

```

b := 124$SingleInteger

```

124

Type: SingleInteger

You can add, multiply and subtract SingleInteger objects, and ask for the greatest common divisor (gcd).

```
gcd(a,b)
2
```

Type: SingleInteger

The least common multiple (lcm) is also available.

```
lcm(a,b)
76508
```

Type: SingleInteger

Operations mulmod, addmod, submod, and invmod are similar - they provide arithmetic modulo a given small integer.

Here is  $5 * 6 \text{ mod } 13$ .

```
mulmod(5,6,13)$SingleInteger
4
```

Type: SingleInteger

To reduce a small integer modulo a prime, use positiveRemainder.

```
positiveRemainder(37,13)$SingleInteger
11
```

Type: SingleInteger

Operations And, Or, xor, and Not provide bit level operations on small integers.

```
And(3,4)$SingleInteger
0
```

Type: SingleInteger

Use shift(int,numToShift) to shift bits, where i is shifted left if numToShift is positive, right if negative.

```
shift(1,4)$SingleInteger
16
```

Type: SingleInteger

```
shift(31,-1)$SingleInteger
15
```

Type: SingleInteger

Many other operations are available for small integers, including many of those provided for Integer.

————— domain SEM SparseEchelonMatrix —————
```

```
)abbrev domain SEM SparseEchelonMatrix
++ Description:
```

```

++ \spad{SparseEchelonMatrix(C, D)} implements sparse matrices whose columns
++ are enumerated by the \spadtype{OrderedSet} \spad{C} and whose entries
++ belong to the \spadtype{GcdDomain} \spad{D}. The basic operation of
++ this domain is the computation of an row echelon form. The used algorithm
++ tries to maintain the sparsity and is especially adapted to matrices who
++ are already close to a row echelon form.

```

```

SparseEchelonMatrix(C : OrderedSet, D : Ring) : Cat == Def where

```

```

Sy ==> Symbol
L ==> List
V ==> Vector
VD ==> Vector D
MD ==> Matrix D
FD ==> Fraction D
MFD ==> Matrix FD
I ==> Integer
NNI ==> NonNegativeInteger
B ==> Boolean
OUT ==> OutputForm

```

```

ROWREC ==> Record(Indices : L C, Entries : L D)

```

```

iter ==> "iterated"::Sy
rand ==> "random"::Sy

```

```

Cat ==> CoercibleTo OUT with

```

```

shallowlyMutable
++ Matrices may be altered destructively.

```

```

finiteAggregate
++ Matrices are finite.

```

```

coerce : % -> MD
++ \spad{coerce(A)} yields the matrix \spad{A} in the usual matrix type.

```

```

copy : % -> %
++ \spad{copy(A)} returns a copy of the matrix \spad{A}.

```

```

ncols : % -> NNI
++ \spad{ncols(A)} returns the number of columns of the matrix \spad{A}.

```

```

nrows : % -> NNI
++ \spad{nrows(A)} returns the number of rows of the matrix \spad{A}.

```

```

allIndices : % -> L C
++ \spad{allIndices(A)} returns all indices used for enumerating the
++ columns of the matrix \spad{A}.

```

```

elimZeroCols! : % -> Void
 ++ \spad{elimZeroCols!(A)} removes columns which contain only zeros.
 ++ This effects basically only the value of \spad{allIndices(A)}.

purge! : (%, C-> B) -> Void
 ++ \spad{purge!(A, crit)} eliminates all columns belonging to an index
 ++ \spad{c} such that \spad{crit(c)} yields \spad{true}.

sortedPurge! : (%, C-> B) -> Void
 ++ \spad{sortedPurge!(A, crit)} is like \spad{purge}, however, with the
 ++ additional assumption that \spad{crit} respects the ordering of the
 ++ indices.

new : (L C, I) -> %
 ++ \spad{new(inds, nrows)} generates a new matrix with \spad{nrows}
 ++ rows and columns enumerated by the indices \spad{inds}. The matrix
 ++ is empty, i.e. the zero matrix.

elt : (%, I, C) -> D
 ++ \spad{elt(A, i, c)} returns the entry of the matrix \spad{A} in row
 ++ \spad{i} and in the column with index \spad{c}.

setelt! : (%, I, C, D) -> Void
 ++ \spad{setelt!(A, i, c, d)} sets the entry of the matrix \spad{A} in
 ++ row \spad{i} and in the column with index \spad{c} to the value
 ++ \spad{d}.

row : (%, I) -> ROWREC
 ++ \spad{row(A, i)} returns the \spad{i}-th row of the matrix \spad{A}.

setRow! : (%, I, ROWREC) -> Void
 ++ \spad{setRow!(A, i, ind, ent)} sets the \spad{i}-th row of the matrix
 ++ \spad{A} to the value \spad{r}.

setRow! : (%, I, L C, L D) -> Void
 ++ \spad{setRow!(A, i, ind, ent)} sets the \spad{i}-th row of the matrix
 ++ \spad{A}. Its indices are \spad{ind}; the entries \spad{ent}.

deleteRow! : (%, I) -> Void
 ++ \spad{deleteRow(A, i)} deletes the \spad{i}-th row of the matrix
 ++ \spad{A}.

consRow! : (%, ROWREC) -> Void
 ++ \spad{consRow!(A, r)} inserts the row \spad{r} at the top of the
 ++ matrix \spad{A}.

appendRow! : (%, ROWREC) -> Void
 ++ \spad{appendRow!(A, r)} appends the row \spad{r} at the end of the
 ++ matrix \spad{A}.

```

```

extract : (% , I, I) -> %
 ++ \spad{extract(A, i1, i2)} extracts the rows \spad{i1} to \spad{i2}
 ++ and returns them as a new matrix.

rowEchelon : % -> Record(Ech : %, Lt : MD, Pivots : L D, Rank : NNI)
 ++ \spad{primitiveRowEchelon(A)} computes a row echelon form for the
 ++ matrix \spad{A}. The algorithm used is fraction-free elimination.
 ++ It is especially adapted to matrices already close to row echelon
 ++ form. The transformation matrix, the used pivots and the rank of the
 ++ matrix are also returned.

if D has GcdDomain then

 setGcdMode : Sy -> Sy
 ++ \spad{setGcdMode(s)} sets a new value for the flag deciding on
 ++ the method used to compute gcd's for lists. Possible values for
 ++ \spad{s} are \spad{iterated} and \spad{random}.

 primitiveRowEchelon: % -> Record(Ech:%, Lt:MFD, Pivots:L D, Rank:NNI)
 ++ \spad{primitiveRowEchelon(A)} computes a row echelon form for the
 ++ matrix \spad{A}. The algorithm used is fraction-free elimination.
 ++ Every row is made primitive by division by the gcd. The algorithm
 ++ is especially adapted to matrices already close to row echelon
 ++ form. The transformation matrix, the used pivots and the rank of the
 ++ matrix are also returned.

 pivot : (% , I) -> Record(Index : C, Entry : D)
 ++ \spad{pivot(A, i)} returns the leading entry of the \spad{i}-th row
 ++ of the matrix \spad{A} together with its index.

 pivots : % -> ROWREC
 ++ \spad{pivots(A)} returns all leading entries of the matrix \spad{A}
 ++ together with their indices.

 "*" : (MD, %) -> %
 ++ \spad{L*A} implements left multiplication with a usual matrix.

if D has IntegralDomain then

 "*" : (MFD, %) -> %
 ++ \spad{L*A} implements left multiplication with a usual matrix over
 ++ the quotient field of \spad{D}.

 join : (% , %) -> %
 ++ \spad{join(A, B)} vertically concats the matrices \spad{A} and
 ++ \spad{B}.

 horizJoin : (% , %) -> %
 ++ \spad{horizJoin(A, B)} horizontally concats the matrices \spad{A} and
 ++ \spad{B}. It is assumed that all indices of \spad{B} are smaller than

```

```

++ those of \spad{A}.

horizSplit : (% , C) -> Record(Left : %, Right : %)
++ \spad{horizSplit(A, c)} splits the matrix \spad{A} into two at the
++ column given by \spad{c}. The first column of the right matrix is
++ enumerated by the first index less or equal to \spad{c}.

SparseMultivariatePolynomial examples
=====

```

This type is the basic representation of sparse recursive multivariate polynomials. It is parameterized by the coefficient ring and the variable set which may be infinite. The variable ordering is determined by the variable set parameter. The coefficient ring may be non-commutative, but the variables are assumed to commute.

=====
SparseMultivariateTaylorSeries examples
=====

```

Assume we have three variables which get expressed as sparse multivariate taylor series.

```

xts:=x::TaylorSeries Fraction Integer
yts:=y::TaylorSeries Fraction Integer
zts:=z::TaylorSeries Fraction Integer

```

These will cause traditional routines to expand in series form:

```
t1:=sin(xts)
```

$$x - \frac{1}{6}x^3 + \frac{1}{120}x^5 - \frac{1}{5040}x^7 + \frac{1}{362880}x^9 + 0(11)$$

We can ask for a specific coefficient, in this case, the coefficient of the third power.

```
coefficient(t1,3)
```

$$-\frac{1}{6}x^3$$

And we can get that coefficient, expressed as a monomial.

```
coefficient(t1,monomial(3,x)$IndexedExponents Symbol)
```

$$-\frac{1}{6}$$

In a multivariate version we get a polynomial in x and y

```
t2:=sin(xts + yts)
```

$$\begin{aligned} & (y + x) + \left( -\frac{1}{6}y^3 - \frac{1}{2}xy^2 - \frac{1}{2}x^2y - \frac{1}{6}x^3 \right) \\ & + \left( \frac{1}{120}y^5 + \frac{1}{24}xy^4 + \frac{1}{12}x^2y^3 + \frac{1}{12}x^3y^2 + \frac{1}{24}x^4y + \frac{1}{120}x^5 \right) \\ & + \text{PAREN} \left( -\frac{1}{5040}y^7 - \frac{1}{720}xy^6 - \frac{1}{240}x^2y^5 - \frac{1}{144}x^3y^4 - \frac{1}{144}x^4y^3 - \frac{1}{240}x^5y^2 \right) \\ & + \left( -\frac{1}{720}x^6y - \frac{1}{5040}x^7 \right) \\ & + \text{PAREN} \left( \frac{1}{362880}y^9 + \frac{1}{40320}xy^8 + \frac{1}{10080}x^2y^7 + \frac{1}{4320}x^3y^6 + \frac{1}{2880}x^4y^5 \right) \\ & + \left( \frac{1}{2880}x^5y^4 + \frac{1}{4320}x^6y^3 + \frac{1}{10080}x^7y^2 + \frac{1}{40320}x^8y + \frac{1}{362880}x^9 \right) \\ & + 0(11) \end{aligned}$$

We can ask for the third coefficient which is

```
coefficient(t2,3)
```

$$-\frac{1}{6}y^3 - \frac{1}{2}xy^2 - \frac{1}{2}x^2y - \frac{1}{6}x^3$$

And we can ask for the third coefficient of that coefficient in x

```
coefficient(t2,monomial(3,x)$IndexedExponents Symbol)
```

$$-\frac{1}{6}$$

And we can convert that result to a polynomial

```
polynomial(t2,5)
```

$$\begin{aligned} & \frac{1}{120}y^5 + \frac{1}{24}xy^4 + \left(-\frac{1}{12}x^2 - \frac{1}{6}\right)y^3 + \left(-\frac{1}{12}x^3 - \frac{1}{2}x\right)y^2 + \left(-\frac{1}{24}x^4 - \frac{1}{2}x^2 + 1\right)y \\ & + \frac{1}{120}x^5 - \frac{1}{6}x^3 + x \end{aligned}$$

— domain SMTS SparseMultivariateTaylorSeries —

```
)abbrev domain SMTS SparseMultivariateTaylorSeries
++ Authors: William Burge, Stephen Watt, Clifton Williamson
++ Date Created: 15 August 1988
++ Date Last Updated: 18 May 1991
++ Description:
++ This domain provides multivariate Taylor series with variables
++ from an arbitrary ordered set. A Taylor series is represented
++ by a stream of polynomials from the polynomial domain SMP.
++ The nth element of the stream is a form of degree n. SMTS is an
++ internal domain.
```

```
SparseMultivariateTaylorSeries(Coef,Var,SMP):_
Exports == Implementation where
 Coef : Ring

— SparseTable.help —

```
=====
SparseTable examples
=====
```

The SparseTable domain provides a general purpose table type with default entries.

Here we create a table to save strings under integer keys. The value "Try again!" is returned if no other value has been stored for a key.

```
t := SparseTable(Integer, String, "Try again!") := table()
table()
 Type: SparseTable(Integer,String,Try again!)
```

Entries can be stored in the table.

```
t.3 := "Number three"
"Number three"
 Type: String
```

```
t.4 := "Number four"
"Number four"
 Type: String
```

These values can be retrieved as usual, but if a look up fails the default entry will be returned.

```
t.3
"Number three"
 Type: String
```

```
t.2
"Try again!"
 Type: String
```

To see which values are explicitly stored, the keys and entries functions can be used.

```
keys t
[4,3]
```

Type: List Integer

```
entries t
 ["Number four","Number three"]
 Type: List String
```

If a specific table representation is required, the `GeneralSparseTable` constructor should be used. The domain `SparseTable(K, E, dflt)` is equivalent to `GeneralSparseTable(K,E,Table(K,E), dflt)`.

=====

SparseUnivariateLaurentSeries examples

=====

SparseUnivariateLaurentSeries is a domain representing Laurent series in one variable with coefficients in an arbitrary ring. The parameters of the type specify the coefficient ring, the power series variable, and the center of the power series expansion. For example, SparseUnivariateLaurentSeries(Integer,x,3) represents Laurent series in  $(x - 3)$  with integer coefficients.

## — domain SULS SparseUnivariateLaurentSeries —

```

)abbrev domain SULS SparseUnivariateLaurentSeries
++ Author: Clifton J. Williamson
++ Date Created: 11 November 1994
++ Date Last Updated: 10 March 1995
++ Description:
++ Sparse Laurent series in one variable
++ \spadtype{SparseUnivariateLaurentSeries} is a domain representing Laurent
++ series in one variable with coefficients in an arbitrary ring. The
++ parameters of the type specify the coefficient ring, the power series
++ variable, and the center of the power series expansion. For example,
++ \spad{SparseUnivariateLaurentSeries(Integer,x,3)} represents Laurent
++ series in \spad{(x - 3)} with integer coefficients.

SparseUnivariateLaurentSeries(Coef,var,cen): Exports == Implementation where
 Coef : Ring
 var : Symbol
 cen : Coef
 I ==> Integer
 NNI ==> NonNegativeInteger
 OUT ==> OutputForm
 P ==> Polynomial Coef
 RF ==> Fraction Polynomial Coef
 RN ==> Fraction Integer
 S ==> String
 SUTS ==> SparseUnivariateTaylorSeries(Coef,var,cen)
 EFULS ==> ElementaryFunctionsUnivariateLaurentSeries(Coef,SUTS,%)

Exports ==> UnivariateLaurentSeriesConstructorCategory(Coef,SUTS) with
 coerce: Variable(var) -> %
 ++ \spad{coerce(var)} converts the series variable \spad{var} into a
 ++ Laurent series.
 differentiate: (% ,Variable(var)) -> %
 ++ \spad{differentiate(f(x),x)} returns the derivative of
 ++ \spad{f(x)} with respect to \spad{x}.
 if Coef has Algebra Fraction Integer then
 integrate: (% ,Variable(var)) -> %
 ++ \spad{integrate(f(x))} returns an anti-derivative of the power
 ++ series \spad{f(x)} with constant coefficient 0.
 ++ We may integrate a series when we can divide coefficients
 ++ by integers.

Implementation ==> InnerSparseUnivariatePowerSeries(Coef) add

SparseUnivariatePolynomial examples
=====
```

This domain represents univariate polynomials over arbitrary (not necessarily commutative) coefficient rings. The variable is unspecified so that the variable displays as ? on output. If it is necessary to specify the variable name, use type UnivariatePolynomial. The representation is sparse in the sense that only non-zero terms are represented. Note that if the coefficient ring is a field, this domain forms a euclidean domain.

)abbrev domain SUP SparseUnivariatePolynomial
++ Author: Dave Barton, Barry Trager
++ Description:
++ This domain represents univariate polynomials over arbitrary
++ (not necessarily commutative) coefficient rings. The variable is
++ unspecified so that the variable displays as \spad{?} on output.
++ If it is necessary to specify the variable name,
++ use type \spadtype{UnivariatePolynomial}. The representation is sparse
++ in the sense that only non-zero terms are represented.
++ Note that if the coefficient ring is a field,
++ this domain forms a euclidean domain.

SparseUnivariatePolynomial(R:Ring): UnivariatePolynomialCategory(R) with
 outputForm : (%,OutputForm) -> OutputForm
 ++ outputForm(p,var) converts the SparseUnivariatePolynomial p to
 ++ an output form (see \spadtype{OutputForm}) printed as a polynomial in the
 ++ output form variable.

## domain SUEXPR SparseUnivariatePolynomialExpressions

This domain is a hack, in some sense. What I'd really like to do - automatically - is to provide all operations supported by the coefficient domain, as long as the polynomials can be retracted to that domain, i.e., as long as they are just constants. I don't see another way to do this, unfortunately.
