=====
SparseUnivariateTaylorSeries examples
=====

```

SparseUnivariateTaylorSeries is a domain representing Taylor series in one variable with coefficients in an arbitrary ring. The parameters of the type specify the coefficient ring, the power series variable, and the center of the power series expansion. For example, SparseUnivariateTaylorSeries(Integer,x,3) represents Taylor series in (x - 3) with Integer coefficients.

## — domain SUTS SparseUnivariateTaylorSeries —

```

)abbrev domain SUTS SparseUnivariateTaylorSeries
++ Author: Clifton J. Williamson
++ Date Created: 16 February 1990
++ Date Last Updated: 10 March 1995
++ Description:
++ Sparse Taylor series in one variable
++ \spadtype{SparseUnivariateTaylorSeries} is a domain representing Taylor
++ series in one variable with coefficients in an arbitrary ring. The
++ parameters of the type specify the coefficient ring, the power series
++ variable, and the center of the power series expansion. For example,
++ \spadtype{SparseUnivariateTaylorSeries}(Integer,x,3) represents Taylor
++ series in \spad{x - 3} with \spadtype{Integer} coefficients.

SparseUnivariateTaylorSeries(Coef,var,cen): Exports == Implementation where
 Coef : Ring
 var : Symbol
 cen : Coef
 COM ==> OrderedCompletion Integer
 I ==> Integer
 L ==> List
 NNI ==> NonNegativeInteger
 OUT ==> OutputForm
 P ==> Polynomial Coef
 REF ==> Reference OrderedCompletion Integer
 RN ==> Fraction Integer
 Term ==> Record(k:Integer,c:Coef)
 SG ==> String
 ST ==> Stream Term
 UP ==> UnivariatePolynomial(var,Coef)

Exports ==> UnivariateTaylorSeriesCategory(Coef) with
 coerce: UP -> %
 ++\spad{coerce(p)} converts a univariate polynomial p in the variable
 ++\spad{var} to a univariate Taylor series in \spad{var}.
 univariatePolynomial: (% ,NNI) -> UP
 ++\spad{univariatePolynomial(f,k)} returns a univariate polynomial
 ++ consisting of the sum of all terms of f of degree \spad{<= k}.
 coerce: Variable(var) -> %
 ++\spad{coerce(var)} converts the series variable \spad{var} into a
 ++ Taylor series.
 differentiate: (% ,Variable(var)) -> %
 ++ \spad{differentiate(f(x),x)} computes the derivative of
 ++ \spad{f(x)} with respect to \spad{x}.
 if Coef has Algebra Fraction Integer then
 integrate: (% ,Variable(var)) -> %
 ++ \spad{integrate(f(x),x)} returns an anti-derivative of the power
 ++ series \spad{f(x)} with constant coefficient 0.

```

```

 ++ We may integrate a series when we can divide coefficients
 ++ by integers.

SplitHomogeneousDirectProduct examples
=====

```

This type represents the finite direct or cartesian product of an underlying ordered component type. The vectors are ordered as if they were split into two blocks. The dim1 parameter specifies the length of the first block. The ordering is lexicographic between the blocks but acts like HomogeneousDirectProduct within each block. This type is a suitable third argument for GeneralDistributedMultivariatePolynomial.

SplittingNode examples

---

This domain exports a modest implementation for the vertices of splitting trees. These vertices are called here splitting nodes. Every of these nodes store 3 informations. The first one is its value, that is the current expression to evaluate. The second one is its condition, that is the hypothesis under which the value has to be evaluated. The last one is its status, that is a boolean flag which is true iff the value is the result of its evaluation under its condition. Two splitting vertices are equal iff they have the same values and the same conditions (so their status do not matter).

=====
SplittingTree examples
=====

```

This domain exports a modest implementation of splitting trees. Splitting trees are needed when the evaluation of some quantity under some hypothesis requires to split the hypothesis into sub-cases. For instance by adding some new hypothesis on one hand and its negation on another hand. The computations are terminated is a splitting tree a when status(value(a)) is true. Thus, if for the splitting tree a the flag status(value(a)) is true, then status(value(d)) is true for any subtree d of a. This property of splitting trees is called the termination condition. If no vertex in a splitting tree a is equal to another, a is said to satisfy the no-duplicates condition. The splitting tree a will satisfy this condition if nodes are added to a by mean of splitNodeOf! and if construct is only used to create the root of a with no children.

++ requires to split the hypothesis into sub-cases.
++ For instance by adding some new hypothesis on one
++ hand and its negation on another hand. The computations
++ are terminated is a splitting tree \axiom{a} when

```

```

++ \axiom{status(value(a))} is \axiom{true}. Thus,
++ if for the splitting tree \axiom{a} the flag
++ \axiom{status(value(a))} is \axiom{true}, then
++ \axiom{status(value(d))} is \axiom{true} for any
++ subtree \axiom{d} of \axiom{a}. This property
++ of splitting trees is called the termination
++ condition. If no vertex in a splitting tree \axiom{a}
++ is equal to another, \axiom{a} is said to satisfy
++ the no-duplicates condition. The splitting
++ tree \axiom{a} will satisfy this condition
++ if nodes are added to \axiom{a} by mean of
++ \axiom{splitNodeOf!} and if \axiom{construct}
++ is only used to create the root of \axiom{a}
++ with no children.

```

SplittingTree(V,C) : Exports == Implementation where

```

V:Join(SetCategory,Aggregate)
C:Join(SetCategory,Aggregate)
B ==> Boolean
O ==> OutputForm
NNI ==> NonNegativeInteger
VT ==> Record(val:V, tower:C)
VTB ==> Record(val:V, tower:C, flag:B)
S ==> SplittingNode(V,C)
A ==> Record(root:S,subTrees:List(%))

```

```

Exports == RecursiveAggregate(S) with
 shallowlyMutable
 finiteAggregate
 extractSplittingLeaf : % -> Union(%, "failed")
 ++ \axiom{extractSplittingLeaf(a)} returns the left
 ++ most leaf (as a tree) whose status is false
 ++ if any, else "failed" is returned.
 updateStatus! : % -> %
 ++ \axiom{updateStatus!(a)} returns a where the status
 ++ of the vertices are updated to satisfy
 ++ the "termination condition".
 construct : S -> %
 ++ \axiom{construct(s)} creates a splitting tree
 ++ with value (i.e. root vertex) given by
 ++ \axiom{s} and no children. Thus, if the
 ++ status of \axiom{s} is false, \axiom{[s]}
 ++ represents the starting point of the
 ++ evaluation \axiom{value(s)} under the
 ++ hypothesis \axiom{condition(s)}.
 construct : (V,C, List %) -> %
 ++ \axiom{construct(v,t,la)} creates a splitting tree
 ++ with value (i.e. root vertex) given by
 ++ \axiom{[v,t]$S} and with \axiom{la} as

```

```

++ children list.
construct : (V,C,List S) -> %
++ \axiom{construct(v,t,ls)} creates a splitting tree
++ with value (i.e. root vertex) given by
++ \axiom{[v,t]$S} and with children list given by
++ \axiom{[[s]$% for s in ls]}.
construct : (V,C,V,List C) -> %
++ \axiom{construct(v1,t,v2,lt)} creates a splitting tree
++ with value (i.e. root vertex) given by
++ \axiom{[v,t]$S} and with children list given by
++ \axiom{[[v,t]$S]$% for s in ls]}.
conditions : % -> List C
++ \axiom{conditions(a)} returns the list of the conditions
++ of the leaves of a
result : % -> List VT
++ \axiom{result(a)} where \axiom{ls} is the leaves list of \axiom{a}
++ returns \axiom{[[value(s),condition(s)]$VT for s in ls]}
++ if the computations are terminated in \axiom{a} else
++ an error is produced.
nodeOf? : (S,%) -> B
++ \axiom{nodeOf?(s,a)} returns true iff some node of \axiom{a}
++ is equal to \axiom{s}
subNodeOf? : (S,%,(C,C) -> B) -> B
++ \axiom{subNodeOf?(s,a,sub?) } returns true iff for some node
++ \axiom{n} in \axiom{a} we have \axiom{s = n} or
++ \axiom{status(n)} and \axiom{subNode?(s,n,sub?)}.
remove : (S,%) -> %
++ \axiom{remove(s,a)} returns the splitting tree obtained
++ from a by removing every sub-tree \axiom{b} such
++ that \axiom{value(b)} and \axiom{s} have the same
++ value, condition and status.
remove! : (S,%) -> %
++ \axiom{remove!(s,a)} replaces a by remove(s,a)
splitNodeOf! : (%,%,List(S)) -> %
++ \axiom{splitNodeOf!(l,a,ls)} returns \axiom{a} where the children
++ list of \axiom{l} has been set to
++ \axiom{[[s]$% for s in ls | not nodeOf?(s,a)]}.
++ Thus, if \axiom{l} is not a node of \axiom{a}, this
++ latter splitting tree is unchanged.
splitNodeOf! : (%,%,List(S),(C,C) -> B) -> %
++ \axiom{splitNodeOf!(l,a,ls,sub?) } returns \axiom{a} where the children
++ list of \axiom{l} has been set to
++ \axiom{[[s]$% for s in ls | not subNodeOf?(s,a,sub?)}}.
++ Thus, if \axiom{l} is not a node of \axiom{a}, this
++ latter splitting tree is unchanged.

=====
SquareFreeRegularTriangularSet examples
=====

```

The SquareFreeRegularTriangularSet domain constructor implements square-free regular triangular sets. See the RegularTriangularSet domain constructor for general regular triangular sets. Let T be a regular triangular set consisting of polynomials  $t_1, \dots, t_m$  ordered by increasing main variables. The regular triangular set T is

square-free if  $T$  is empty or if  $t_1, \dots, t_{m-1}$  is square-free and if the polynomial  $t_m$  is square-free as a univariate polynomial with coefficients in the tower of simple extensions associated with  $t_1, \dots, t_{m-1}$ .

The main interest of square-free regular triangular sets is that their associated towers of simple extensions are product of fields. Consequently, the saturated ideal of a square-free regular triangular set is radical. This property simplifies some of the operations related to regular triangular sets. However, building square-free regular triangular sets is generally more expensive than building general regular triangular sets.

As the `RegularTriangularSet` domain constructor, the `SquareFreeRegularTriangularSet` domain constructor also implements a method for solving polynomial systems by means of regular triangular sets. This is in fact the same method with some adaptations to take into account the fact that the computed regular chains are square-free. Note that it is also possible to pass from a decomposition into general regular triangular sets to a decomposition into square-free regular triangular sets. This conversion is used internally by the `LazardSetSolvingPackage` package constructor.

N.B. When solving polynomial systems with the `SquareFreeRegularTriangularSet` domain constructor or the `LazardSetSolvingPackage` package constructor, decompositions have no redundant components. See also `LexTriangularPackage` and `ZeroDimensionalSolvePackage` for the case of algebraic systems with a finite number of (complex) solutions.

We shall explain now how to use the constructor `SquareFreeRegularTriangularSet`.

This constructor takes four arguments. The first one,  $R$ , is the coefficient ring of the polynomials; it must belong to the category `GcdDomain`. The second one,  $E$ , is the exponent monoid of the polynomials; it must belong to the category `OrderedAbelianMonoidSup`. The third one,  $V$ , is the ordered set of variables; it must belong to the category `OrderedSet`. The last one is the polynomial ring; it must belong to the category `RecursivePolynomialCategory(R,E,V)`. The abbreviation for `SquareFreeRegularTriangularSet` is `SREGSET`.

Note that the way of understanding triangular decompositions is detailed in the example of the `RegularTriangularSet` constructor.

Let us illustrate the use of this constructor with one example (Donati-Traverso). Define the coefficient ring.

```
R := Integer
Integer
Type: Domain
```

Define the list of variables,

```
ls : List Symbol := [x,y,z,t]
 [x,y,z,t]
 Type: List Symbol
```

and make it an ordered set;

```
V := OVAR(ls)
 OrderedVariableList [x,y,z,t]
 Type: Domain
```

then define the exponent monoid.

```
E := IndexedExponents V
 IndexedExponents OrderedVariableList [x,y,z,t]
 Type: Domain
```

Define the polynomial ring.

```
P := NSMP(R, V)
 NewSparseMultivariatePolynomial(Integer,OrderedVariableList [x,y,z,t])
 Type: Domain
```

Let the variables be polynomial.

```
x: P := 'x
 x
 Type: NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t])
```

```
y: P := 'y
 y
 Type: NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t])
```

```
z: P := 'z
 z
 Type: NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t])
```

```
t: P := 't
 t
 Type: NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t])
```

Now call the SquareFreeRegularTriangularSet domain constructor.

```
ST := SREGSET(R,E,V,P)
 SquareFreeRegularTriangularSet(Integer,IndexedExponents OrderedVariableList [
```

```
x,y,z,t],OrderedVariableList [x,y,z,t],NewSparseMultivariatePolynomial(Integer,
r,OrderedVariableList [x,y,z,t]))
```

```
Type: Domain
```

Define a polynomial system.

```
p1 := x ** 31 - x ** 6 - x - y
 31 6
x - x - x - y
 Type: NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t])
```

```
p2 := x ** 8 - z
 8
x - z
 Type: NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t])
```

```
p3 := x ** 10 - t
 10
x - t
 Type: NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t])
```

```
lp := [p1, p2, p3]
 31 6 8 10
[x - x - x - y, x - z, x - t]
 Type: List NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t])
```

First of all, let us solve this system in the sense of Kalkbrener.

```
zeroSetSplit(lp)$ST
 5 4 2 3 8 5 3 2 4 2
[{z - t , t z y + 2z y - t + 2t + t - t , (t - t)x - t y - z }]
 Type: List SquareFreeRegularTriangularSet(Integer,
 IndexedExponents OrderedVariableList [x,y,z,t],
 OrderedVariableList [x,y,z,t],
 NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t]))
```

And now in the sense of Lazard (or Wu and other authors).

```
zeroSetSplit(lp,false)$ST
 5 4 2 3 8 5 3 2 4 2
[{z - t , t z y + 2z y - t + 2t + t - t , (t - t)x - t y - z },
 3 5 2 2
{t - 1, z - t, t y + z , z x - t}, {t,z,y,x}]
 Type: List SquareFreeRegularTriangularSet(Integer,
 IndexedExponents OrderedVariableList [x,y,z,t],
```

```
OrderedVariableList [x,y,z,t],
NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t]))
```

Now to see the difference with the RegularTriangularSet domain constructor, we define:

```
T := REGSET(R,E,V,P)
RegularTriangularSet(Integer,IndexedExponents OrderedVariableList [x,y,z,t],O
rderedVariableList [x,y,z,t],NewSparseMultivariatePolynomial(Integer,OrderedV
ariableList [x,y,z,t]))
Type: Domain
```

and compute:

```
lts := zeroSetSplit(lp,false)$T
 5 4 2 3 8 5 3 2 4 2
 [z - t ,t z y + 2z y - t + 2t + t - t ,(t - t)x - t y - z },
 3 5 2 3 2
 {t - 1,z - t,t z y + 2z y + 1,z x - t}, {t,z,y,x}]
Type: List RegularTriangularSet(Integer,
IndexedExponents OrderedVariableList [x,y,z,t],
OrderedVariableList [x,y,z,t],
NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t]))
```

If you look at the second set in both decompositions in the sense of Lazard, you will see that the polynomial with main variable y is not the same.

Let us understand what has happened.

We define:

```
ts := lts.2
 3 5 2 3 2
(19) {t - 1,z - t,t z y + 2z y + 1,z x - t}
Type: RegularTriangularSet(Integer,
IndexedExponents OrderedVariableList [x,y,z,t],
OrderedVariableList [x,y,z,t],
NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t]))

pol := select(ts,'y)$T
 2 3
 t z y + 2z y + 1
Type: Union(NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t]),...)

tower := collectUnder(ts,'y)$T
 3 5
```

```

{t - 1, z - t}
Type: RegularTriangularSet(Integer,
 IndexedExponents OrderedVariableList [x,y,z,t],
 OrderedVariableList [x,y,z,t],
 NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t]))

pack := RegularTriangularSetGcdPackage(R,E,V,P,T)
RegularTriangularSetGcdPackage(Integer,IndexedExponents OrderedVariableList [
x,y,z,t],OrderedVariableList [x,y,z,t],NewSparseMultivariatePolynomial(Intege
r,OrderedVariableList [x,y,z,t]),RegularTriangularSet(Integer,IndexedExponent
s OrderedVariableList [x,y,z,t],OrderedVariableList [x,y,z,t],NewSparseMultiv
ariatePolynomial(Integer,OrderedVariableList [x,y,z,t]))
Type: Domain

```

Then we compute:

```

toseSquareFreePart(pol,tower)$pack
 2 3 5
[[val= t y + z ,tower= {t - 1,z - t}]]
Type: List Record(val: NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t]),
 tower: RegularTriangularSet(Integer,
 IndexedExponents OrderedVariableList [x,y,z,t],
 OrderedVariableList [x,y,z,t],
 NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t])))

```

=====

SquareMatrix examples

=====

The top level matrix type in Axiom is Matrix, which provides basic arithmetic and linear algebra functions. However, since the matrices can be of any size it is not true that any pair can be added or multiplied. Thus Matrix has little algebraic structure.

Sometimes you want to use matrices as coefficients for polynomials or in other algebraic contexts. In this case, SquareMatrix should be

used. The domain SquareMatrix(n,R) gives the ring of n by n square matrices over R.

Since SquareMatrix is not normally exposed at the top level, you must expose it before it can be used.

```
)set expose add constructor SquareMatrix
```

Once SQMATRIX has been exposed, values can be created using the squareMatrix function.

```
m := squareMatrix [[1,-%i],[%i,4]]
+1 - %i+
| |
+%i 4 +
Type: SquareMatrix(2,Complex Integer)
```

The usual arithmetic operations are available.

```
m*m - m
+ 1 - 4%i+
| |
+4%i 13 +
Type: SquareMatrix(2,Complex Integer)
```

Square matrices can be used where ring elements are required. For example, here is a matrix with matrix entries.

```
mm := squareMatrix [[m, 1], [1-m, m**2]]
++1 - %i+ +1 0+ +
|| | | |
|+%i 4 + +0 1+ |
| | |
|+ 0 %i + + 2 - 5%i+|
|| | | ||
++- %i - 3+ +5%i 17 ++
Type: SquareMatrix(2,SquareMatrix(2,Complex Integer))
```

Or you can construct a polynomial with square matrix coefficients.

```
p := (x + m)**2
2 + 2 - 2%i+ + 2 - 5%i+
x + | |x + | |
+2%i 8 + +5%i 17 +
Type: Polynomial SquareMatrix(2,Complex Integer)
```

This value can be converted to a square matrix with polynomial coefficients.

```
p::SquareMatrix(2, ?)
+ 2 +
```

```

|x + 2x + 2 - 2%i x - 5%i|
| |
| 2 |
+2%i x + 5%i x + 8x + 17 +
Type: SquareMatrix(2,Polynomial Complex Integer)

```

## — domain SQMATRIX SquareMatrix —

```

)abbrev domain SQMATRIX SquareMatrix
++ Author: Grabmeier, Gschnitzer, Williamson
++ Date Created: 1987
++ Date Last Updated: July 1990
++ Description:
++ \spadtype{SquareMatrix} is a matrix domain of square matrices, where the
++ number of rows (= number of columns) is a parameter of the type.

SquareMatrix(ndim,R): Exports == Implementation where
 ndim : NonNegativeInteger
 R : Ring
 Row ==> DirectProduct(ndim,R)
 Col ==> DirectProduct(ndim,R)
 MATLIN ==> MatrixLinearAlgebraFunctions(R,Row,Col,$)

Exports ==> Join(SquareMatrixCategory(ndim,R,Row,Col),_
 CoercibleTo Matrix R) with

transpose: $ -> $
 ++ \spad{transpose(m)} returns the transpose of the matrix m.
squareMatrix: Matrix R -> $
 ++ \spad{squareMatrix(m)} converts a matrix of type \spadtype{Matrix}
 ++ to a matrix of type \spadtype{SquareMatrix}.
coerce: $ -> Matrix R
 ++ \spad{coerce(m)} converts a matrix of type \spadtype{SquareMatrix}
 ++ to a matrix of type \spadtype{Matrix}.
-- symdecomp : $ -> Record(sym:$,antisym:$)
-- ++ \spad{symdecomp(m)} decomposes the matrix m as a sum of a symmetric
-- ++ matrix \spad{m1} and an antisymmetric matrix \spad{m2}. The object
-- ++ returned is the Record \spad{[m1,m2]}

```

```

-- if R has commutative("*") then
-- minorsVect: -> Vector(Union(R,"uncomputed")) --range: 1..2**n-1
-- ++ \spad{minorsVect(m)} returns a vector of the minors of the matrix m
if R has commutative("*") then central
 ++ the elements of the Ring R, viewed as diagonal matrices, commute
 ++ with all matrices and, indeed, are the only matrices which commute
 ++ with all matrices.
if R has commutative("*") and R has unitsKnown then unitsKnown
 ++ the invertible matrices are simply the matrices whose determinants
 ++ are units in the Ring R.
if R has ConvertibleTo InputForm then ConvertibleTo InputForm

Implementation ==> Matrix R add
 minr ==> minRowIndex
 maxr ==> maxRowIndex
 minc ==> minColIndex
 maxc ==> maxColIndex
 mini ==> minIndex
 maxi ==> maxIndex

=====
Stack examples
=====

```

A Stack object is represented as a list ordered by last-in, first-out. It operates like a pile of books, where the "next" book is the one on the top of the pile.

Here we create a stack of integers from a list. Notice that the order in the list is the order in the stack.

```

a:Stack INT:= stack [1,2,3,4,5]
[1,2,3,4,5]

```

We can remove the top of the stack using pop!:

```

pop! a
1

```

Notice that the use of pop! is destructive (destructive operations in Axiom usually end with ! to indicate that the underlying data

structure is changed).

```
a
 [2,3,4,5]
```

The `extract!` operation is another name for the `pop!` operation and has the same effect. This operation treats the stack as a `BagAggregate`:

```
extract! a
 2
```

and you can see that it also has destructively modified the stack:

```
a
 [3,4,5]
```

Next we push a new element on top of the stack:

```
push!(9,a)
 9
```

Again, the `push!` operation is destructive so the stack is changed:

```
a
 [9,2,3,4,5]
```

Another name for `push!` is `insert!`, which treats the stack as a `BagAggregate`:

```
insert!(8,a)
 [8,9,3,4,5]
```

and it modifies the stack:

```
a
 [8,9,3,4,5]
```

The `inspect` function returns the top of the stack without modification, viewed as a `BagAggregate`:

```
inspect a
 8
```

The `empty?` operation returns true only if there are no element on the stack, otherwise it returns false:

```
empty? a
 false
```

The `top` operation returns the top of stack without modification, viewed as a `Stack`:

```
top a
 8
```

The depth operation returns the number of elements on the stack:

```
depth a
 5
```

which is the same as the # (length) operation:

```
#a
 5
```

The less? predicate will compare the stack length to an integer:

```
less?(a,9)
 true
```

The more? predicate will compare the stack length to an integer:

```
more?(a,9)
 false
```

The size? operation will compare the stack length to an integer:

```
size?(a,#a)
 true
```

and since the last computation must always be true we try:

```
size?(a,9)
 false
```

The parts function will return the stack as a list of its elements:

```
parts a
 [8,9,3,4,5]
```

If we have a BagAggregate of elements we can use it to construct a stack. Notice that the elements are pushed in reverse order:

```
bag([1,2,3,4,5])$Stack(INT)
 [5,4,3,2,1]
```

The empty function will construct an empty stack of a given type:

```
b:=empty()$(Stack INT)
 []
```

and the `empty?` predicate allows us to find out if a stack is empty:

```
empty? b
 true
```

The `sample` function returns a sample, empty stack:

```
sample()$Stack(INT)
 []
```

We can copy a stack and it does not share storage so subsequent modifications of the original stack will not affect the copy:

```
c:=copy a
 [8,9,3,4,5]
```

The `eq?` function is only true if the lists are the same reference, so even though `c` is a copy of `a`, they are not the same:

```
eq?(a,c)
 false
```

However, `a` clearly shares a reference with itself:

```
eq?(a,a)
 true
```

But we can compare `a` and `c` for equality:

```
(a=c)@Boolean
 true
```

and clearly `a` is equal to itself:

```
(a=a)@Boolean
 true
```

and since `a` and `c` are equal, they are clearly NOT not-equal:

```
a~c
 false
```

We can use the `any?` function to see if a predicate is true for any element:

```
any?(x+->(x=4),a)
 true
```

or false for every element:

```
any?(x+->(x=11),a)
```

```
false
```

We can use the `every?` function to check every element satisfies a predicate:

```
every?(x-->(x=11),a)
false
```

We can count the elements that are equal to an argument of this type:

```
count(4,a)
1
```

or we can count against a boolean function:

```
count(x-->(x>2),a)
5
```

You can also map a function over every element, returning a new stack:

```
map(x-->x+10,a)
[18,19,13,14,15]
```

Notice that the original stack is unchanged:

```
a
[8,9,3,4,5]
```

You can use `map!` to map a function over every element and change the original stack since `map!` is destructive:

```
map!(x-->x+10,a)
[18,19,13,14,15]
```

Notice that the original stack has been changed:

```
a
[18,19,13,14,15]
```

The `members` function can also get the element of the stack as a list:

```
members a
[18,19,13,14,15]
```

and using `member?` we can test if the stack holds a given element:

```
member?(14,a)
true
```

=====
StochasticDifferential examples
=====

```

A basic implementation of StochasticDifferential(R) using the associated domain BasicStochasticDifferential in the underlying representation as sparse multivariate polynomials. The domain is a module over Expression(R), and is a ring without identity (AXIOM term is "Rng"). Note that separate instances, for example using R=Integer and R=Float, have different hidden structure (multiplication and drift tables).

```

— domain SD StochasticDifferential —

```

)abbrev domain SD StochasticDifferential
++ Author: Wilfrid S. Kendall
++ Last Last Updated: July 26, 1999
++ Related Domains: BasicStochasticDifferential
++ References: Ito (1975), Kendall (1991a,b; 1993a,b).
++ Description:
++ A basic implementation of StochasticDifferential(R) using the
++ associated domain BasicStochasticDifferential in the underlying
++ representation as sparse multivariate polynomials. The domain is
++ a module over Expression(R), and is a ring without identity
++ (AXIOM term is "Rng"). Note that separate instances, for example
++ using R=Integer and R=Float, have different hidden structure
++ (multiplication and drift tables).

```

```

StochasticDifferential(R:Join(OrderedSet, IntegralDomain)):
 Category == Implementation where

```

```

ER ==> Expression(R)
PR ==> Polynomial(R)
FR ==> Fraction(PR)
BSD ==> BasicStochasticDifferential
PI ==> PositiveInteger
NNI ==> NonNegativeInteger
OF ==> OutputForm
Category ==> Join(Rng, Module(ER)) with

RetractableTo(BSD)

alterQuadVar!:(BSD,BSD,%) -> Union(%, "failed")
++ alterQuadVar! adds multiplication formula for a
++ pair of stochastic differentials to a private table.
++ Failure occurs if
++ (a) either of first or second arguments is not basic
++ (b) third argument is not exactly of first degree

alterDrift!:(BSD,%) -> Union(%, "failed")
++ alterDrift! adds drift formula for a
++ stochastic differential to a private table.
++ Failure occurs if
++ (a) first arguments is not basic
++ (b) second argument is not exactly of first degree

drift:% -> %
++ drift(dx) returns the drift of \axiom{dx}

freeOf?:(% ,BSD) -> Boolean
++ freeOf?(sd,dX) checks whether \axiom{dX} occurs in
++ \axiom{sd} as a module element

coefficient:(%,BSD) -> ER
++ coefficient(sd,dX) returns the coefficient of \axiom{dX}
++ in the stochastic differential \axiom{sd}

listSD:(%) -> List BSD
++ listSD(dx) returns a list of all \axiom{BSD} involved
++ in the generation of \axiom{dx} as a module element

equation:(%,R) -> Union(Equation %, "failed")
++ equation(dx,0) allows RHS of Equation % to be zero
equation:(R,%) -> Union(Equation %, "failed")
++ equation(0,dx) allows LHS of Equation % to be zero

copyDrift:() -> Table(%,%)
++ copyDrift returns private table of drifts
++ of basic stochastic differentials for inspection

copyQuadVar:() -> Table(%,%)

```

```

++ copyQuadVar returns private multiplication table
++ of basic stochastic differentials for inspection

"/" : (% , ER) -> %
++ dx/y divides the stochastic differential dx
++ by the previsible function y.

"*)" : (% , PI) -> %
++ dx**n is dx multiplied by itself n times.

"^" : (% , PI) -> %
++ dx^n is dx multiplied by itself n times.

statusIto:() -> OF
++ statusIto() displays the current state of \axiom{setBSD},
++ \axiom{tableDrift}, and \axiom{tableQuadVar}. Question
++ marks are printed instead of undefined entries
++
++X dt:=introduce!(t,dt)
++X dX:=introduce!(X,dX)

=====
Stream examples
=====

```

A Stream object is represented as a list whose last element contains the wherewithal to create the next element, should it ever be required.

Let ints be the infinite stream of non-negative integers.

```

ints := [i for i in 0..]
 [0,1,2,3,4,5,6,7,8,9,...]

```

Type: Stream NonNegativeInteger

By default, ten stream elements are calculated. This number may be changed to something else by the system command

```
)set streams calculate
```

More generally, you can construct a stream by specifying its initial value and a function which, when given an element, creates the next element.

```
f : List INT -> List INT
 Type: Void

f x == [x.1 + x.2, x.1]
 Type: Void

fibs := [i.2 for i in [generate(f,[1,1])]]
 [1,1,2,3,5,8,13,21,34,55,...]
 Type: Stream Integer
```

You can create the stream of odd non-negative integers by either filtering them from the integers, or by evaluating an expression for each integer.

```
[i for i in ints | odd? i]
 [1,3,5,7,9,11,13,15,17,19,...]
 Type: Stream NonNegativeInteger

odds := [2*i+1 for i in ints]
 [1,3,5,7,9,11,13,15,17,19,...]
 Type: Stream NonNegativeInteger
```

You can accumulate the initial segments of a stream using the scan operation.

```
scan(0,+,odds)
 [1,4,9,16,25,36,49,64,81,100,...]
 Type: Stream NonNegativeInteger
```

The corresponding elements of two or more streams can be combined in this way.

```
[i*j for i in ints for j in odds]
 [0,3,10,21,36,55,78,105,136,171,...]
 Type: Stream NonNegativeInteger

map(*,ints,odds)
 [0,3,10,21,36,55,78,105,136,171,...]
 Type: Stream NonNegativeInteger
```

Many operations similar to those applicable to lists are available for streams.

```
first ints
 0
```

Type: NonNegativeInteger

```
rest ints
 [1,2,3,4,5,6,7,8,9,10,...]
```

Type: Stream NonNegativeInteger

```
fibs 20
 6765
```

Type: PositiveInteger

=====
String examples
=====
```

The type `String` provides character strings. Character strings provide all the operations for a one-dimensional array of characters, plus additional operations for manipulating text.

String values can be created using double quotes.

```
hello := "Hello, I'm AXIOM!"
 "Hello, I'm AXIOM!"
 Type: String
```

Note, however, that double quotes and underscores must be preceded by an extra underscore.

```
said := "Jane said, \"Look!\""
 "Jane said, \"Look!\""
 Type: String
```

```
saw := "She saw exactly one underscore: \"_\"."
 "She saw exactly one underscore: \"_\"."
 Type: String
```

It is also possible to use `new` to create a string of any size filled with a given character. Since there are many new functions it is necessary to indicate the desired type.

```
gasp: String := new(32, char "x")
 "xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx"
 Type: String
```

The length of a string is given by `#`.

```
#gasp
32
 Type: PositiveInteger
```

Indexing operations allow characters to be extracted or replaced in strings. For any string `s`, indices lie in the range `1..#s`.

```
hello.2
e
 Type: Character
```

Indexing is really just the application of a string to a subscript, so any application syntax works.

```
hello 2
```

```
e
 Type: Character
```

```
hello(2)
e
 Type: Character
```

If it is important not to modify a given string, it should be copied before any updating operations are used.

```
hullo := copy hello
 "Hello, I'm AXIOM!"
 Type: String
```

```
hullo.2 := char "u"; [hello, hullo]
 ["Hello, I'm AXIOM!","Hullo, I'm AXIOM!"]
 Type: List String
```

Operations are provided to split and join strings. The concat operation allows several strings to be joined together.

```
sajdsaw := concat ["alpha","---","omega"]
 "alpha---omega"
 Type: String
```

There is a version of concat that works with two strings.

```
concat("hello ","goodbye")
 "hello goodbye"
 Type: String
```

Juxtaposition can also be used to concatenate strings.

```
"This " "is " "several " "strings " "concatenated."
 "This is several strings concatenated."
 Type: String
```

Substrings are obtained by giving an index range.

```
hello(1..5)
 "Hello"
 Type: String
```

```
hello(8..)
 "I'm AXIOM!"
 Type: String
```

A string can be split into several substrings by giving a separation character or character class.

```
split(hello, char " ")
["Hello","I'm","AXIOM!"]
Type: List String
```

```
other := complement alphanumeric();
Type: CharacterClass
```

```
split(saidsaw, other)
["alpha","omega"]
Type: List String
```

Unwanted characters can be trimmed from the beginning or end of a string using the operations `trim`, `leftTrim` and `rightTrim`.

```
trim("## ++ relax ++ ##", char "#")
" ++ relax ++ "
Type: String
```

Each of these functions takes a string and a second argument to specify the characters to be discarded.

```
trim("## ++ relax ++ ##", other)
"relax"
Type: String
```

The second argument can be given either as a single character or as a character class.

```
leftTrim("## ++ relax ++ ##", other)
"relax ++ ##"
Type: String
```

```
rightTrim("## ++ relax ++ ##", other)
"## ++ relax"
Type: String
```

Strings can be changed to upper case or lower case using the operations `upperCase` and `lowerCase`.

```
upperCase hello
"HELLO, I'M AXIOM!"
Type: String
```

The versions with the exclamation mark change the original string, while the others produce a copy.

```
lowerCase hello
"hello, i'm axiom!"
Type: String
```

Some basic string matching is provided. The function `prefix?` tests whether one string is an initial prefix of another.

```
prefix?("He", "Hello")
 true
 Type: Boolean
```

```
prefix?("Her", "Hello")
 false
 Type: Boolean
```

A similar function, `suffix?`, tests for suffixes.

```
suffix?("", "Hello")
 true
 Type: Boolean
```

```
suffix?("LO", "Hello")
 false
 Type: Boolean
```

The function `substring?` tests for a substring given a starting position.

```
substring?("ll", "Hello", 3)
 true
 Type: Boolean
```

```
substring?("ll", "Hello", 4)
 false
 Type: Boolean
```

A number of position functions locate things in strings. If the first argument to `position` is a string, then `position(s,t,i)` finds the location of `s` as a substring of `t` starting the search at position `i`.

```
n := position("nd", "underground", 1)
 2
 Type: PositiveInteger
```

```
n := position("nd", "underground", n+1)
 10
 Type: PositiveInteger
```

If `s` is not found, then 0 is returned (`minIndex(s)-1` in `IndexedString`).

```
n := position("nd", "underground", n+1)
 0
 Type: NonNegativeInteger
```

To search for a specific character or a member of a character class,

a different first argument is used.

```
position(char "d", "underground", 1)
3
Type: PositiveInteger
```

```
position(hexDigit(), "underground", 1)
3
Type: PositiveInteger
```

— **StringTable.help** —

=====  
StringTable examples  
=====

This domain provides a table type in which the keys are known to be strings so special techniques can be used. Other than performance, the type StringTable(S) should behave exactly the same way as Table(String,S).

This creates a new table whose keys are strings.

```
t: StringTable(Integer) := table()
 table()
```

Type: StringTable Integer

The value associated with each string key is the number of characters in the string.

```
for s in split("My name is Ian Watt.",char " ")
 repeat
 t.s := #s
```

Type: Void

```
for key in keys t repeat output [key, t.key]
["Watt.",5]
["Ian",3]
["is",2]
["name",4]
["My",2]
```

Type: Void

## domain SUBSPACE SubSpace

The first argument *n* is the dimension of the subSpace

The SubSpace domain is implemented as a tree. The root of the tree is the only node in which the field *dataList* - which points to a list of points over the ring, *R* - is defined. The children of the root are the top level components of the SubSpace (in 2D, these would be separate curves; in 3D, these would be separate surfaces).

The *pt* field is only defined in the leaves.

By way of example, consider a three dimensional subspace with two components - a three by three grid and a sphere. The internal representation of this subspace is a tree with a depth of three.

The root holds a list of all the points used in the subspace (so, if the grid and the sphere share points, the shared points would not be represented redundantly but would be referenced by index).

The root, in this case, has two children - the first points to the grid component and the second to the sphere component. The grid child has four children of its own - a 3x3 grid has 4 endpoints - and each of these point to a list of four points. To see it another way, the grid (child of the root) holds a list of line components which, when placed one above the next, forms a grid. Each of these line components is a list of points.

Points could be explicitly added to subspaces at any level. A path could be given as an argument to the `addPoint()` function. It is a list of `NonNegativeIntegers` and refers, in order, to the *n*-th child of the current node. For example,

```
addPoint(s,[2,3],p)
```

would add the point *p* to the subspace *s* by going to the second child of the root and then the third child of that node. If the path does extend to the full depth of the tree, nodes are automatically added so that the tree is of constant depth down any path. By not specifying the full path, new components could be added - e.g. for *s* from `SubSpace(3,Float)`

```
addPoint(s,[],p)
```

would create a new child to the root (a new component in *N*-space) and extend a path to a leaf of depth 3 that points to the data held in *p*. The subspace *s* would now have a new

component which has one child which, in turn, has one child (the leaf). The new component is then a point.

 ++ merge(ls) a list of subspaces, ls, into one subspace.
 separate : % -> List %
 ++ separate(s) makes each of the components of the \spadtype{SubSpace},
 ++ s, into a list of separate and distinct subspaces and returns
 ++ the list.
 addPoint : (% , List NNI , POINT) -> %
 ++ addPoint(s,li,p) adds the 4 dimensional point, p, to the 3

```

```

++ dimensional subspace, s. The list of non negative integers, li,
++ dictates the path to follow, or, to look at it another way,
++ points to the component in which the point is to be added. It's
++ length should range from 0 to \spad{n - 1} where n is the dimension
++ of the subspace. If the length is \spad{n - 1}, then a specific
++ lowest level component is being referenced. If it is less than
++ \spad{n - 1}, then some higher level component (0 indicates top
++ level component) is being referenced and a component of that level
++ with the desired point is created. The subspace s is returned
++ with the additional point.
addPoint2 : (%,POINT) -> %
++ addPoint2(s,p) adds the 4 dimensional point, p, to the 3
++ dimensional subspace, s.
++ The subspace s is returned with the additional point.
addPointLast : (%,%,POINT, NNI) -> %
++ addPointLast(s,s2,li,p) adds the 4 dimensional point, p, to the 3
++ dimensional subspace, s. s2 point to the end of the subspace
++ s. n is the path in the s2 component.
++ The subspace s is returned with the additional point.
modifyPoint : (%,List NNI,POINT) -> %
++ modifyPoint(s,li,p) replaces an existing point in the 3 dimensional
++ subspace, s, with the 4 dimensional point, p. The list of non
++ negative integers, li, dictates the path to follow, or, to look at
++ it another way, points to the component in which the existing point
++ is to be modified. An error message occurs if s is empty, otherwise
++ the subspace s is returned with the point modification.
addPoint : (%,List NNI,NNI) -> %
++ addPoint(s,li,i) adds the 4 dimensional point indicated by the
++ index location, i, to the 3 dimensional subspace, s. The list of
++ non negative integers, li, dictates the path to follow, or, to
++ look at it another way, points to the component in which the point
++ is to be added. It's length should range from 0 to \spad{n - 1}
++ where n is the dimension of the subspace. If the length is
++ \spad{n - 1}, then a specific lowest level component is being
++ referenced. If it is less than \spad{n - 1}, then some higher
++ level component (0 indicates top level component) is being
++ referenced and a component of that level with the desired point
++ is created. The subspace s is returned with the additional point.
modifyPoint : (%,List NNI,NNI) -> %
++ modifyPoint(s,li,i) replaces an existing point in the 3 dimensional
++ subspace, s, with the 4 dimensional point indicated by the index
++ location, i. The list of non negative integers, li, dictates
++ the path to follow, or, to look at it another way, points to the
++ component in which the existing point is to be modified. An error
++ message occurs if s is empty, otherwise the subspace s is returned
++ with the point modification.
addPoint : (%,POINT) -> NNI
++ addPoint(s,p) adds the point, p, to the 3 dimensional subspace, s,
++ and returns the new total number of points in s.
modifyPoint : (%,NNI,POINT) -> %

```

```

++ modifyPoint(s,ind,p) modifies the point referenced by the index
++ location, ind, by replacing it with the point, p in the 3 dimensional
++ subspace, s. An error message occurs if s is empty, otherwise the
++ subspace s is returned with the point modification.

closeComponent : (%,List NNI,B) -> %
++ closeComponent(s,li,b) sets the property of the component in the
++ 3 dimensional subspace, s, to be closed if b is true, or open if
++ b is false. The list of non negative integers, li, dictates the
++ path to follow, or, to look at it another way, points to the
++ component whose closed property is to be set. The subspace, s,
++ is returned with the component property modification.
defineProperty : (%,List NNI,PROP) -> %
++ defineProperty(s,li,p) defines the component property in the
++ 3 dimensional subspace, s, to be that of p, where p is of the
++ domain \spadtype{SubSpaceComponentProperty}. The list of non
++ negative integers, li, dictates the path to follow, or, to look
++ at it another way, points to the component whose property is
++ being defined. The subspace, s, is returned with the component
++ property definition.
traverse : (%,List NNI) -> %
++ traverse(s,li) follows the branch list of the 3 dimensional
++ subspace, s, along the path dictated by the list of non negative
++ integers, li, which points to the component which has been
++ traversed to. The subspace, s, is returned, where s is now
++ the subspace pointed to by li.
extractPoint : % -> POINT
++ extractPoint(s) returns the point which is given by the current
++ index location into the point data field of the 3 dimensional
++ subspace s.
extractIndex : % -> NNI
++ extractIndex(s) returns a non negative integer which is the current
++ index of the 3 dimensional subspace s.
extractClosed : % -> B
++ extractClosed(s) returns the \spadtype{Boolean} value of the closed
++ property for the indicated 3 dimensional subspace s. If the
++ property is closed, \spad{True} is returned, otherwise \spad{False}
++ is returned.
extractProperty : % -> PROP
++ extractProperty(s) returns the property of domain
++ \spadtype{SubSpaceComponentProperty} of the indicated 3 dimensional
++ subspace s.
level : % -> NNI
++ level(s) returns a non negative integer which is the current
++ level field of the indicated 3 dimensional subspace s.
parent : % -> %
++ parent(s) returns the subspace which is the parent of the indicated
++ 3 dimensional subspace s. If s is the top level subspace an error
++ message is returned.
pointData : % -> L POINT

```

```

++ pointData(s) returns the list of points from the point data field
++ of the 3 dimensional subspace s.

Symbol examples

---

Symbols are one of the basic types manipulated by Axiom. The Symbol domain provides ways to create symbols of many varieties.

The simplest way to create a symbol is to "single quote" an identifier.

```

X: Symbol := 'x
x

```

Type: Symbol

This gives the symbol even if x has been assigned a value. If x has not been assigned a value, then it is possible to omit the quote.

```
XX: Symbol := x
 x
 Type: Symbol
```

Declarations must be used when working with symbols, because otherwise the interpreter tries to place values in a more specialized type Variable.

```
A := 'a
 a
 Type: Variable a
```

```
B := b
 b
 Type: Variable b
```

The normal way of entering polynomials uses this fact.

```
x**2 + 1
 2
 x + 1
 Type: Polynomial Integer
```

Another convenient way to create symbols is to convert a string. This is useful when the name is to be constructed by a program.

```
"Hello"::Symbol
 Hello
 Type: Symbol
```

Sometimes it is necessary to generate new unique symbols, for example, to name constants of integration. The expression new() generates a symbol starting with %.

```
new()$Symbol
 %A
 Type: Symbol
```

Successive calls to new produce different symbols.

```
new()$Symbol
 %B
 Type: Symbol
```

The expression new("s") produces a symbol starting with %s.

```
new("xyz")$Symbol
 %xyz0
```

Type: Symbol

A symbol can be adorned in various ways. The most basic thing is applying a symbol to a list of subscripts.

```
X[i,j]
 x
 i,j
```

Type: Symbol

Somewhat less pretty is to attach subscripts, superscripts or arguments.

```
U := subscript(u, [1,2,1,2])
 u
 1,2,1,2
```

Type: Symbol

```
V := superscript(v, [n])
 n
 v
```

Type: Symbol

```
P := argscript(p, [t])
 p(t)
```

Type: Symbol

It is possible to test whether a symbol has scripts using the `scripted?` test.

```
scripted? U
 true
```

Type: Boolean

```
scripted? X
 false
```

Type: Boolean

If a symbol is not scripted, then it may be converted to a string.

```
string X
 "x"
```

Type: String

The basic parts can always be extracted using the `name` and `scripts` operations.

```
name U
 u
```

Type: Symbol

```
scripts U
 [sub= [1,2,1,2],sup= [],presup= [],presub= [],args= []]
```

```

Type: Record(sub: List OutputForm,
 sup: List OutputForm,
 presup: List OutputForm,
 presub: List OutputForm,
 args: List OutputForm)

```

```

name X
 x

```

```

Type: Symbol

```

```

scripts X
[sub= [],sup= [],presup= [],presub= [],args= []]
Type: Record(sub: List OutputForm,
 sup: List OutputForm,
 presup: List OutputForm,
 presub: List OutputForm,
 args: List OutputForm)

```

The most general form is obtained using the script operation. This operation takes an argument which is a list containing, in this order, lists of subscripts, superscripts, presuperscripts, presubscripts and arguments to a symbol.

```

M := script(Mammoth, [[i,j],[k,l],[0,1],[2],[u,v,w]])
 0,1 k,l
 Mammoth (u,v,w)
 2 i,j

```

```

Type: Symbol

```

```

scripts M
[sub= [i,j],sup= [k,l],presup= [0,1],presub= [2],args= [u,v,w]]
Type: Record(sub: List OutputForm,
 sup: List OutputForm,
 presup: List OutputForm,
 presub: List OutputForm,
 args: List OutputForm)

```

If trailing lists of scripts are omitted, they are assumed to be empty.

```

N := script(Nut, [[i,j],[k,l],[0,1]])
 0,1 k,l
 Nut
 i,j

```

```

Type: Symbol

```

```

scripts N
[sub= [i,j],sup= [k,l],presup= [0,1],presub= [],args= []]
Type: Record(sub: List OutputForm,
 sup: List OutputForm,
 presup: List OutputForm,

```

```
presub: List OutputForm,
args: List OutputForm)
```

=====

```

The Table constructor provides a general structure for associative storage. This type provides hash tables in which data objects can be saved according to keys of any type. For a given table, specific types must be chosen for the keys and entries.

In this example the keys to the table are polynomials with integer coefficients. The entries in the table are strings.

```

t: Table(Polynomial Integer, String) := table()
table()
Type: Table(Polynomial Integer,String)

```

To save an entry in the table, the setelt operation is used. This can be called directly, giving the table a key and an entry.

```

setelt(t, x**2 - 1, "Easy to factor")
"Easy to factor"
Type: String

```

Alternatively, you can use assignment syntax.

```

t(x**3 + 1) := "Harder to factor"
"Harder to factor"
Type: String

```

```

t(x) := "The easiest to factor"
"The easiest to factor"
Type: String

```

Entries are retrieved from the table by calling the `elt` operation.

```
elt(t, x)
 "The easiest to factor"
 Type: String
```

This operation is called when a table is "applied" to a key using this or the following syntax.

```
t.x
 "The easiest to factor"
 Type: String
```

```
t x
 "The easiest to factor"
 Type: String
```

Parentheses are used only for grouping. They are needed if the key is an infix expression.

```
t.(x**2 - 1)
 "Easy to factor"
 Type: String
```

Note that the `elt` operation is used only when the key is known to be in the table, otherwise an error is generated.

```
t (x**3 + 1)
 "Harder to factor"
 Type: String
```

You can get a list of all the keys to a table using the `keys` operation.

```
keys t
 3 2
 [x,x + 1,x - 1]
 Type: List Polynomial Integer
```

If you wish to test whether a key is in a table, the `search` operation is used. This operation returns either an entry or "failed".

```
search(x, t)
 "The easiest to factor"
 Type: Union(String,...)
```

```
search(x**2, t)
 "failed"
 Type: Union("failed",...)
```

The return type is a union so the success of the search can be tested

using case.

```
search(x**2, t) case "failed"
 true
 Type: Boolean
```

The remove operation is used to delete values from a table.

```
remove!(x**2-1, t)
 "Easy to factor"
 Type: Union(String,...)
```

If an entry exists under the key, then it is returned. Otherwise remove returns "failed".

```
remove!(x-1, t)
 "failed"
 Type: Union("failed",...)
```

The number of key-entry pairs can be found using the # operation.

```
#t
 2
 Type: PositiveInteger
```

Just as keys returns a list of keys to the table, a list of all the entries can be obtained using the members operation.

```
members t
(17) ["The easiest to factor","Harder to factor"]
 Type: List String
```

A number of useful operations take functions and map them on to the table to compute the result. Here we count the entries which have "Hard" as a prefix.

```
count(s: String +-> prefix?("Hard", s), t)
 1
 Type: PositiveInteger
```

Other table types are provided to support various needs.

- o AssociationList gives a list with a table view. This allows new entries to be appended onto the front of the list to cover up old entries. This is useful when table entries need to be stacked or when frequent list traversals are required.
- o EqTable gives tables in which keys are considered equal only when they are in fact the same instance of a structure.
- o StringTable should be used when the keys are known to be strings.
- o SparseTable provides tables with default entries, so lookup never fails. The GeneralSparseTable constructor can be used to make any table type

- behave this way.
- o KeyedAccessFile allows values to be saved in a file, accessed as a table.

## domain TEX TexFormat

### product(product(i\*j,i=a..b),j=c..d) fix

The expression prints properly in ascii text but the tex output is incorrect. Originally the input

```
product(product(i*j,i=a..b),j=c..d)
```

prints as

$$(1) \quad PI2(j = c, d, PI2(i = a, b, i j))$$

but now says: The problem is in `[[src/algebra/tex.spad.pamphlet]]` in the list of constants. The code used to read

```
plexOps : L S := ["SIGMA","SIGMA2","PI","INTSIGN","INDEFINTEGRAL"]$(L S)
plexPrecs : L I := [700, 800, 700, 700]$(L I)
```

it now reads:

— **product(product(i\*j,i=a..b),j=c..d) fix** —

```
plexOps : L S := ["SIGMA","SIGMA2","PI","PI2","INTSIGN","INDEFINTEGRAL"]$(L S)
plexPrecs : L I := [700, 800, 700, 800 , 700, 700]$(L I)
```

in addition we need to add a line defining `[[PI2]]` in `[[formatPlex]]`:

— **define PI2** —

```
op = "PI2" => "\prod"
```

— **TexFormat.input** —

```

```

```
["$$","\frac{{x+3}}{{y -5}} ", "$$"]
```

We can change the fraction display so it is horizontal:

```
)set output fraction horizontal
```

```
(1/2)::TEX
```

```
["$$","SLASH ", "\left(", "{1, \: 2} ", "\right)", "$$"]
```

```
(1/(x+5))::TEX
```

```
["$$","SLASH ","\left(","{1, \: {x+5}} ","\right)","$$"]
```

```
((x+3)/(y-5))::TEX
```

```
["$$","SLASH ","\left(","{x+3}, \: {y -5}} ","\right)","$$"]
```

— domain **TEX** TexFormat —

```

)abbrev domain TEX TexFormat
++ Author: Robert S. Sutor
++ Date Created: 1987 through 1992
++ Description:
++ \spadtype{TexFormat} provides a coercion from \spadtype{OutputForm} to
++ \TeX{} format. The particular dialect of \TeX{} used is \LaTeX{}.
++ The basic object consists of three parts: a prologue, a
++ tex part and an epilogue. The functions \spadfun{prologue},
++ \spadfun{tex} and \spadfun{epilogue} extract these parts,
++ respectively. The main guts of the expression go into the tex part.

```

```

++ The other parts can be set (\spadfun{setPrologue!},
++ \spadfun{setEpilogue!}) so that contain the appropriate tags for
++ printing. For example, the prologue and epilogue might simply
++ contain ‘\verb+[+’ and ‘\verb+[]+’, respectively, so that
++ the TeX section will be printed in LaTeX display math mode.

```

```

TexFormat(): public == private where

```

```

E ==> OutputForm
I ==> Integer
L ==> List
S ==> String
US ==> UniversalSegment(Integer)

```

```

public == SetCategory with

```

```

coerce: E -> $
++ coerce(o) changes o in the standard output format to TeX
++ format.

```

```

convert: (E,I) -> $
++ convert(o,step) changes o in standard output format to
++ TeX format and also adds the given step number. This is useful
++ if you want to create equations with given numbers or have the
++ equation numbers correspond to the interpreter step numbers.

```

```

convert: (E,I,E) -> $
++ convert(o,step,type) changes o in standard output format to
++ TeX format and also adds the given step number and type. This
++ is useful if you want to create equations with given numbers
++ or have the equation numbers correspond to the interpreter step
++ numbers.

```

```

display: ($, I) -> Void
++ display(t,width) outputs the TeX formatted code t so that each
++ line has length less than or equal to \spadvar{width}.

```

```

display: $ -> Void
++ display(t) outputs the TeX formatted code t so that each
++ line has length less than or equal to the value set by
++ the system command \spadsyscom{set output length}.

```

```

epilogue: $ -> L S
++ epilogue(t) extracts the epilogue section of a TeX form t.

```

```

tex: $ -> L S
++ tex(t) extracts the TeX section of a TeX form t.

```

```

new: () -> $
++ new() create a new, empty object. Use \spadfun{setPrologue!},
++ \spadfun{setTex!} and \spadfun{setEpilogue!} to set the various

```

```

 ++ components of this object.

prologue: $ -> L S
 ++ prologue(t) extracts the prologue section of a TeX form t.

setEpilogue!: ($, L S) -> L S
 ++ setEpilogue!(t,strings) sets the epilogue section of a TeX form t
 ++ to strings.

setTex!: ($, L S) -> L S
 ++ setTex!(t,strings) sets the TeX section of a TeX form t to strings.

setPrologue!: ($, L S) -> L S
 ++ setPrologue!(t,strings) sets the prologue section of a TeX form t
 ++ to strings.

```
=====
TextFile examples
=====
```

The domain TextFile allows Axiom to read and write character data and exchange text with other programs. This type behaves in Axiom much like a File of strings, with additional operations to cause new lines. We give an example of how to produce an upper case copy of a file.

This is the file from which we read the text.

```
f1: TextFile := open("/etc/group", "input")
"/etc/group"
Type: TextFile
```

This is the file to which we write the text.

```
f2: TextFile := open("/tmp/MOTD", "output")
"MOTD"
Type: TextFile
```

Entire lines are handled using the readLine and writeLine operations.

```
l := readLine! f1
"root:x:0:root"
Type: String
```

```
writeLine!(f2, upperCase l)
"ROOT:X:0:ROOT"
Type: String
```

Use the endOfFile? operation to check if you have reached the end of the file.

```
while not endOfFile? f1 repeat
 s := readLine! f1
 writeLine!(f2, upperCase s)
Type: Void
```

The file f1 is exhausted and should be closed.

```
close! f1
"/etc/group"
```

Type: TextFile

It is sometimes useful to write lines a bit at a time. The write operation allows this.

```
write!(f2, "-The-")
"-The-"
```

Type: String

```
write!(f2, "-End-")
"-End-"
```

Type: String

This ends the line. This is done in a machine-dependent manner.

```
writeLine! f2
""
```

Type: String

```
close! f2
"MOTD"
```

Type: TextFile

Finally, clean up.

```
)system rm /tmp/MOTD
```

— domain TEXTFILE TextFile —

```

)abbrev domain TEXTFILE TextFile
++ Author: Stephen M. Watt
++ Date Created: 1985
++ Date Last Updated: June 4, 1991
++ Description:
++ This domain provides an implementation of text files. Text is stored
++ in these files using the native character set of the computer.

TextFile: Cat == Def where
 StreamName ==> Union(FileName, "console")

 Cat == FileCategory(FileName, String) with
 writeLine_!: (%, String) -> String
 ++ writeLine!(f,s) writes the contents of the string s
 ++ and finishes the current line in the file f.
 ++ The value of s is returned.

 writeLine_!: % -> String
 ++ writeLine!(f) finishes the current line in the file f.
 ++ An empty string is returned. The call \spad{writeLine!(f)} is
 ++ equivalent to \spad{writeLine!(f,"")}.

```

```

readLine_!: % -> String
 ++ readLine!(f) returns a string of the contents of a line from
 ++ the file f.

readLineIfCan_!: % -> Union(String, "failed")
 ++ readLineIfCan!(f) returns a string of the contents of a line from
 ++ file f, if possible. If f is not readable or if it is
 ++ positioned at the end of file, then \spad{"failed"} is returned.

readIfCan_!: % -> Union(String, "failed")
 ++ readIfCan!(f) returns a string of the contents of a line from
 ++ file f, if possible. If f is not readable or if it is
 ++ positioned at the end of file, then \spad{"failed"} is returned.

endOfFile?: % -> Boolean
 ++ endOfFile?(f) tests whether the file f is positioned after the
 ++ end of all text. If the file is open for output, then
 ++ this test is always true.

Exports ==> SetCategory with
viewThetaDefault : () -> F
 ++ viewThetaDefault() returns the current default longitudinal
 ++ view angle in radians.
viewThetaDefault : F -> F
 ++ viewThetaDefault(t) sets the current default longitudinal
 ++ view angle in radians to the value t and returns t.
viewPhiDefault : () -> F
 ++ viewPhiDefault() returns the current default latitudinal
 ++ view angle in radians.
viewPhiDefault : F -> F
 ++ viewPhiDefault(p) sets the current default latitudinal
 ++ view angle in radians to the value p and returns p.
viewZoomDefault : () -> F
 ++ viewZoomDefault() returns the current default graph scaling
 ++ value.
viewZoomDefault : F -> F
 ++ viewZoomDefault(s) sets the current default graph scaling
 ++ value to s and returns s.
viewDeltaXDefault : () -> F
 ++ viewDeltaXDefault() returns the current default horizontal
 ++ offset from the center of the viewport window.
viewDeltaXDefault : F -> F
 ++ viewDeltaXDefault(dx) sets the current default horizontal
 ++ offset from the center of the viewport window to be \spad{dx}
 ++ and returns \spad{dx}.
viewDeltaYDefault : () -> F
 ++ viewDeltaYDefault() returns the current default vertical
 ++ offset from the center of the viewport window.
viewDeltaYDefault : F -> F
 ++ viewDeltaYDefault(dy) sets the current default vertical

```

```

++ offset from the center of the viewport window to be \spad{dy}
++ and returns \spad{dy}.
viewport3D : () -> %
++ viewport3D() returns an undefined three-dimensional viewport
++ of the domain \spadtype{ThreeDimensionalViewport} whose
++ contents are empty.
makeViewport3D : % -> %
++ makeViewport3D(v) takes the given three-dimensional viewport,
++ v, of the domain \spadtype{ThreeDimensionalViewport} and
++ displays a viewport window on the screen which contains
++ the contents of v.
makeViewport3D : (SPACE3,S) -> %
++ makeViewport3D(sp,s) takes the given space, \spad{sp} which is
++ of the domain \spadtype{ThreeSpace} and displays a viewport
++ window on the screen which contains the contents of \spad{sp},
++ and whose title is given by s.
makeViewport3D : (SPACE3,L DROP) -> %
++ makeViewport3D(sp,lopt) takes the given space, \spad{sp} which is
++ of the domain \spadtype{ThreeSpace} and displays a viewport
++ window on the screen which contains the contents of \spad{sp},
++ and whose draw options are indicated by the list \spad{lopt}, which
++ is a list of options from the domain \spad{DrawOption}.
subspace : % -> SPACE3
++ subspace(v) returns the contents of the viewport v, which is
++ of the domain \spadtype{ThreeDimensionalViewport}, as a subspace
++ of the domain \spad{ThreeSpace}.
subspace : (% ,SPACE3) -> %
++ subspace(v,sp) places the contents of the viewport v, which is
++ of the domain \spadtype{ThreeDimensionalViewport}, in the subspace
++ \spad{sp}, which is of the domain \spad{ThreeSpace}.
modifyPointData : (% ,NNI,POINT) -> Void
++ modifyPointData(v,ind,pt) takes the viewport, v, which is of the
++ domain \spadtype{ThreeDimensionalViewport}, and places the data
++ point, \spad{pt} into the list of points database of v at the index
++ location given by \spad{ind}.
options : % -> L DROP
++ options(v) takes the viewport, v, which is of the domain
++ \spadtype{ThreeDimensionalViewport} and returns a list of all
++ the draw options from the domain \spad{DrawOption} which are
++ being used by v.
options : (% ,L DROP) -> %
++ options(v,lopt) takes the viewport, v, which is of the domain
++ \spadtype{ThreeDimensionalViewport} and sets the draw options
++ being used by v to those indicated in the list, \spad{lopt},
++ which is a list of options from the domain \spad{DrawOption}.
move : (% ,NNI,NNI) -> Void
++ move(v,x,y) displays the three-dimensional viewport, v, which
++ is of domain \spadtype{ThreeDimensionalViewport}, with the upper
++ left-hand corner of the viewport window at the screen
++ coordinate position x, y.

```

```

resize : (% ,PI,PI) -> Void
++ resize(v,w,h) displays the three-dimensional viewport, v, which
++ is of domain \spadtype{ThreeDimensionalViewport}, with a width
++ of w and a height of h, keeping the upper left-hand corner
++ position unchanged.
title : (% ,S) -> Void
++ title(v,s) changes the title which is shown in the three-dimensional
++ viewport window, v of domain \spadtype{ThreeDimensionalViewport}.
dimensions : (% ,NNI,NNI,PI,PI) -> Void
++ dimensions(v,x,y,width,height) sets the position of the
++ upper left-hand corner of the three-dimensional viewport, v,
++ which is of domain \spadtype{ThreeDimensionalViewport}, to
++ the window coordinate x, y, and sets the dimensions of the
++ window to that of \spad{width}, \spad{height}. The new
++ dimensions are not displayed until the function
++ \spadfun{makeViewport3D} is executed again for v.
viewpoint : (% ,F,F,F,F,F) -> Void
++ viewpoint(v,th,phi,s,dx,dy) sets the longitudinal view angle
++ to \spad{th} radians, the latitudinal view angle to \spad{phi}
++ radians, the scale factor to \spad{s}, the horizontal viewport
++ offset to \spad{dx}, and the vertical viewport offset to \spad{dy}
++ for the viewport v, which is of the domain
++ \spadtype{ThreeDimensionalViewport}. The new viewpoint position
++ is not displayed until the function \spadfun{makeViewport3D} is
++ executed again for v.
viewpoint : (%) -> V
++ viewpoint(v) returns the current viewpoint setting of the given
++ viewport, v. This function is useful in the situation where the
++ user has created a viewport, proceeded to interact with it via
++ the control panel and desires to save the values of the viewpoint
++ as the default settings for another viewport to be created using
++ the system.
viewpoint : (% ,V) -> Void
++ viewpoint(v,viewpt) sets the viewpoint for the viewport. The
++ viewport record consists of the latitudal and longitudinal angles,
++ the zoom factor, the x,y and z scales, and the x and y displacements.
viewpoint : (% ,I,I,F,F,F) -> Void
++ viewpoint(v,th,phi,s,dx,dy) sets the longitudinal view angle
++ to \spad{th} degrees, the latitudinal view angle to \spad{phi}
++ degrees, the scale factor to \spad{s}, the horizontal viewport
++ offset to \spad{dx}, and the vertical viewport offset to \spad{dy}
++ for the viewport v, which is of the domain
++ \spadtype{ThreeDimensionalViewport}. The new viewpoint position
++ is not displayed until the function \spadfun{makeViewport3D} is
++ executed again for v.
viewpoint : (% ,F,F) -> Void
++ viewpoint(v,th,phi) sets the longitudinal view angle to \spad{th}
++ radians and the latitudinal view angle to \spad{phi} radians
++ for the viewport v, which is of the domain
++ \spadtype{ThreeDimensionalViewport}. The new viewpoint position

```

```

++ is not displayed until the function \spadfun{makeViewport3D} is
++ executed again for v.
viewpoint : (%F,F,F) -> Void
++ viewpoint(v,rotx,roty,rotz) sets the rotation about the x-axis
++ to be \spad{rotx} radians, sets the rotation about the y-axis
++ to be \spad{roty} radians, and sets the rotation about the z-axis
++ to be \spad{rotz} radians, for the viewport v, which is of the
++ domain \spadtype{ThreeDimensionalViewport} and displays v with
++ the new view position.
controlPanel : (%S) -> Void
++ controlPanel(v,s) displays the control panel of the given
++ three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}, if s is "on", or hides
++ the control panel if s is "off".
axes : (%S) -> Void
++ axes(v,s) displays the axes of the given three-dimensional
++ viewport, v, which is of domain \spadtype{ThreeDimensionalViewport},
++ if s is "on", or does not display the axes if s is "off".
diagonals : (%S) -> Void
++ diagonals(v,s) displays the diagonals of the polygon outline
++ showing a triangularized surface instead of a quadrilateral
++ surface outline, for the given three-dimensional viewport v
++ which is of domain \spadtype{ThreeDimensionalViewport}, if s is
++ "on", or does not display the diagonals if s is "off".
outlineRender : (%S) -> Void
++ outlineRender(v,s) displays the polygon outline showing either
++ triangularized surface or a quadrilateral surface outline depending
++ on the whether the \spadfun{diagonals} function has been set, for
++ the given three-dimensional viewport v which is of domain
++ \spadtype{ThreeDimensionalViewport}, if s is "on", or does not
++ display the polygon outline if s is "off".
drawStyle : (%S) -> Void
++ drawStyle(v,s) displays the surface for the given three-dimensional
++ viewport v which is of domain \spadtype{ThreeDimensionalViewport}
++ in the style of drawing indicated by s. If s is not a valid
++ drawing style the style is wireframe by default. Possible
++ styles are \spad{"shade"}, \spad{"solid"} or \spad{"opaque"},
++ \spad{"smooth"}, and \spad{"wireMesh"}.
rotate : (%F,F) -> Void
++ rotate(v,th,phi) rotates the graph to the longitudinal view angle
++ \spad{th} radians and the latitudinal view angle \spad{phi} radians
++ for the viewport v, which is of the domain
++ \spadtype{ThreeDimensionalViewport}.
rotate : (%I,I) -> Void
++ rotate(v,th,phi) rotates the graph to the longitudinal view angle
++ \spad{th} degrees and the latitudinal view angle \spad{phi} degrees
++ for the viewport v, which is of the domain
++ \spadtype{ThreeDimensionalViewport}. The new rotation position
++ is not displayed until the function \spadfun{makeViewport3D} is
++ executed again for v.

```

```

zoom : (% ,F) -> Void
++ zoom(v,s) sets the graph scaling factor to s, for the viewport v,
++ which is of the domain \spadtype{ThreeDimensionalViewport}.
zoom : (% ,F,F,F) -> Void
++ zoom(v,sx,sy,sz) sets the graph scaling factors for the x-coordinate
++ axis to \spad{sx}, the y-coordinate axis to \spad{sy} and the
++ z-coordinate axis to \spad{sz} for the viewport v, which is of
++ the domain \spadtype{ThreeDimensionalViewport}.
translate : (% ,F,F) -> Void
++ translate(v,dx,dy) sets the horizontal viewport offset to \spad{dx}
++ and the vertical viewport offset to \spad{dy}, for the viewport v,
++ which is of the domain \spadtype{ThreeDimensionalViewport}.
perspective : (% ,S) -> Void
++ perspective(v,s) displays the graph in perspective if s is "on",
++ or does not display perspective if s is "off" for the given
++ three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}.
eyeDistance : (% ,F) -> Void
++ eyeDistance(v,d) sets the distance of the observer from the center
++ of the graph to d, for the viewport v, which is of the domain
++ \spadtype{ThreeDimensionalViewport}.
hitherPlane : (% ,F) -> Void
++ hitherPlane(v,h) sets the hither clipping plane of the graph to h,
++ for the viewport v, which is of the domain
++ \spadtype{ThreeDimensionalViewport}.
showRegion : (% ,S) -> Void
++ showRegion(v,s) displays the bounding box of the given
++ three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}, if s is "on", or does not
++ display the box if s is "off".
showClipRegion : (% ,S) -> Void
++ showClipRegion(v,s) displays the clipping region of the given
++ three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}, if s is "on", or does not
++ display the region if s is "off".
clipSurface : (% ,S) -> Void
++ clipSurface(v,s) displays the graph with the specified
++ clipping region removed if s is "on", or displays the graph
++ without clipping implemented if s is "off", for the given
++ three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}.
lighting : (% ,F,F,F) -> Void
++ lighting(v,x,y,z) sets the position of the light source to
++ the coordinates x, y, and z and displays the graph for the given
++ three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}.
intensity : (% ,F) -> Void
++ intensity(v,i) sets the intensity of the light source to i, for
++ the given three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}.

```

```

reset : % -> Void
 ++ reset(v) sets the current state of the graph characteristics
 ++ of the given three-dimensional viewport, v, which is of domain
 ++ \spadtype{ThreeDimensionalViewport}, back to their initial settings.
colorDef : (% ,C,C) -> Void
 ++ colorDef(v,c1,c2) sets the range of colors along the colormap so
 ++ that the lower end of the colormap is defined by \spad{c1} and the
 ++ top end of the colormap is defined by \spad{c2}, for the given
 ++ three-dimensional viewport, v, which is of domain
 ++ \spadtype{ThreeDimensionalViewport}.
write : (% ,S) -> S
 ++ write(v,s) takes the given three-dimensional viewport, v, which
 ++ is of domain \spadtype{ThreeDimensionalViewport}, and creates
 ++ a directory indicated by s, which contains the graph data
 ++ file for v.
write : (% ,S,S) -> S
 ++ write(v,s,f) takes the given three-dimensional viewport, v, which
 ++ is of domain \spadtype{ThreeDimensionalViewport}, and creates
 ++ a directory indicated by s, which contains the graph data
 ++ file for v and an optional file type f.
write : (% ,S,L S) -> S
 ++ write(v,s,lf) takes the given three-dimensional viewport, v, which
 ++ is of domain \spadtype{ThreeDimensionalViewport}, and creates
 ++ a directory indicated by s, which contains the graph data
 ++ file for v and the optional file types indicated by the list lf.
close : % -> Void
 ++ close(v) closes the viewport window of the given
 ++ three-dimensional viewport, v, which is of domain
 ++ \spadtype{ThreeDimensionalViewport}, and terminates the
 ++ corresponding process ID.
key : % -> I
 ++ key(v) returns the process ID number of the given three-dimensional
 ++ viewport, v, which is of domain \spadtype{ThreeDimensionalViewport}.
-- print : % -> Void

— TwoDimensionalArray.help —

```
=====
TwoDimensionalArray examples
=====
```

The TwoDimensionalArray domain is used for storing data in a two dimensional data structure indexed by row and by column. Such an array is a homogeneous data structure in that all the entries of the array must belong to the same Axiom domain.. Each array has a fixed number of rows and columns specified by the user and arrays are not extensible. In Axiom, the indexing of two-dimensional arrays is one-based. This means that both the "first" row of an array and the "first" column of an array are given the index 1. Thus, the entry in the upper left corner of an array is in position (1,1).

The operation new creates an array with a specified number of rows and columns and fills the components of that array with a specified entry. The arguments of this operation specify the number of rows, the number of columns, and the entry.

This creates a five-by-four array of integers, all of whose entries are zero.

```
arr : ARRAY2 INT := new(5,4,0)
+0 0 0 0+
| |
|0 0 0 0|
| |
|0 0 0 0|
| |
|0 0 0 0|
| |
+0 0 0 0+
```

Type: TwoDimensionalArray Integer

The entries of this array can be set to other integers using setelt.

Issue this to set the element in the upper left corner of this array to 17.

```
setelt(arr,1,1,17)
17
```

Type: PositiveInteger

Now the first element of the array is 17.

```
arr
 +17 0 0 0+
 | | |
 |0 0 0 0|
 | | |
 |0 0 0 0|
 | | |
 |0 0 0 0|
 | | |
 +0 0 0 0+
 Type: TwoDimensionalArray Integer
```

Likewise, elements of an array are extracted using the operation `elt`.

```
elt(arr,1,1)
17
 Type: PositiveInteger
```

Another way to use these two operations is as follows. This sets the element in position (3,2) of the array to 15.

```
arr(3,2) := 15
15
 Type: PositiveInteger
```

This extracts the element in position (3,2) of the array.

```
arr(3,2)
15
 Type: PositiveInteger
```

The operations `elt` and `setelt` come equipped with an error check which verifies that the indices are in the proper ranges. For example, the above array has five rows and four columns, so if you ask for the entry in position (6,2) with `arr(6,2)` Axiom displays an error message. If there is no need for an error check, you can call the operations `qelt` and `qsetelt` which provide the same functionality but without the error check. Typically, these operations are called in well-tested programs.

The operations `row` and `column` extract rows and columns, respectively, and return objects of `OneDimensionalArray` with the same underlying element type.

```
row(arr,1)
[17,0,0,0]
 Type: OneDimensionalArray Integer
```

```
column(arr,1)
```

```
[17,0,0,0,0]
```

```
Type: OneDimensionalArray Integer
```

You can determine the dimensions of an array by calling the operations `nrows` and `ncols`, which return the number of rows and columns, respectively.

```
nrows(arr)
```

```
5
```

```
Type: PositiveInteger
```

```
ncols(arr)
```

```
4
```

```
Type: PositiveInteger
```

To apply an operation to every element of an array, use `map`. This creates a new array. This expression negates every element.

```
map(-,arr)
```

```
+ 17 0 0 0+
|
| 0 0 0 0|
|
| 0 -15 0 0|
|
| 0 0 0 0|
|
+ 0 0 0 0+
```

```
Type: TwoDimensionalArray Integer
```

This creates an array where all the elements are doubled.

```
map((x +> x + x),arr)
```

```
+34 0 0 0+
|
| 0 0 0 0|
|
| 0 30 0 0|
|
| 0 0 0 0|
|
+0 0 0 0+
```

```
Type: TwoDimensionalArray Integer
```

To change the array destructively, use `map!` instead of `map`. If you need to make a copy of any array, use `copy`.

```
arrc := copy(arr)
```

```
+17 0 0 0+
|
| 0 0 0 0|
```

```

|
|0 15 0 0|
|
|0 0 0 0|
|
+0 0 0 0+

```

Type: TwoDimensionalArray Integer

map!(-,arrc)

```

+- 17 0 0 0+
|
| 0 0 0 0|
|
| 0 -15 0 0|
|
| 0 0 0 0|
|
+ 0 0 0 0+

```

Type: TwoDimensionalArray Integer

arrc

```

+- 17 0 0 0+
|
| 0 0 0 0|
|
| 0 -15 0 0|
|
| 0 0 0 0|
|
+ 0 0 0 0+

```

Type: TwoDimensionalArray Integer

arr

```

+17 0 0 0+
|
|0 0 0 0|
|
|0 15 0 0|
|
|0 0 0 0|
|
+0 0 0 0+

```

Type: TwoDimensionalArray Integer

Use member? to see if a given element is in an array.

member?(17,arr)

true

Type: Boolean

```
member?(10317,arr)
false
Type: Boolean
```

To see how many times an element appears in an array, use count.

```
count(17,arr)
1
Type: PositiveInteger
```

```
count(0,arr)
18
Type: PositiveInteger
```

— domain ARRAY2 TwoDimensionalArray —

```
)abbrev domain ARRAY2 TwoDimensionalArray
++ Author: Mark Botch
++ Description:
++ A TwoDimensionalArray is a two dimensional array with
++ 1-based indexing for both rows and columns.

TwoDimensionalArray(R):Exports == Implementation where
 R : Type
 Row ==> OneDimensionalArray R
 Col ==> OneDimensionalArray R

Exports ==> TwoDimensionalArrayCategory(R,Row,Col) with
 shallowlyMutable
 ++ One may destructively alter TwoDimensionalArray's.

Implementation ==> InnerIndexedTwoDimensionalArray(R,1,1,Row,Col)
```

=====
TwoDimensionalViewport examples
=====
```

We want to graph  $x^3 * (a+b*x)$  on the interval  $x=-1..1$   
so we clear out the workspace

We assign values to the constants

```
a:=0.5
0.5
 Type: Float
```

```
b:=0.5
0.5
 Type: Float
```

We draw the first case of the graph

```
y1:=draw(x^3*(a+b*x),x=-1..1,title=="2.2.10 explicit")
TwoDimensionalViewport: "2.2.10 explicit"
 Type: TwoDimensionalViewport
```

We fetch the graph of the first object

```
g1:=getGraph(y1,1)
Graph with 1 point list
 Type: GraphImage
```

We extract its points

```
pointLists g1

```

Type: List List Point DoubleFloat

Now we create a second graph with a changed parameter

```

b:=1.0
1.0

```

Type: Float

We draw it

```

y2:=draw(x^3*(a+b*x),x=-1..1)
TwoDimensionalViewport: "AXIOM2D"

```

Type: TwoDimensionalViewport

We fetch this new graph

```
g2:=getGraph(y2,1)
 Graph with 1 point list
 Type: GraphImage
```

We get the points from this graph

```
pointLists g2

getPickedPoints : $ -> L POINT
 ++ getPickedPoints(x)
 ++ returns a list of small floats for the points the
 ++ user interactively picked on the viewport
 ++ for full integration into the system, some design
 ++ issues need to be addressed: e.g. how to go through
 ++ the GraphImage interface, how to default to graphs, etc.
viewport2D : () -> $
 ++ viewport2D() returns an undefined two-dimensional viewport
 ++ of the domain \spadtype{TwoDimensionalViewport} whose
 ++ contents are empty.
makeViewport2D : $ -> $
 ++ makeViewport2D(v) takes the given two-dimensional viewport,
 ++ v, of the domain \spadtype{TwoDimensionalViewport} and
 ++ displays a viewport window on the screen which contains
 ++ the contents of v.
options : $ -> L DROP
 ++ options(v) takes the given two-dimensional viewport, v, of the
 ++ domain \spadtype{TwoDimensionalViewport} and returns a list
 ++ containing the draw options from the domain \spadtype{DrawOption}
 ++ for v.
options(v,lopt) : ($,L DROP) -> $
 ++ options(v,lopt) takes the given two-dimensional viewport, v,
 ++ of the domain \spadtype{TwoDimensionalViewport} and returns
 ++ v with it's draw options modified to be those which are indicated
 ++ in the given list, \spad{lopt} of domain \spadtype{DrawOption}.
makeViewport2D : (G,L DROP) -> $
 ++ makeViewport2D(gi,lopt) creates and displays a viewport window
 ++ of the domain \spadtype{TwoDimensionalViewport} whose graph
 ++ field is assigned to be the given graph, \spad{gi}, of domain
 ++ \spadtype{GraphImage}, and whose options field is set to be
 ++ the list of options, \spad{lopt} of domain \spadtype{DrawOption}.
graphState : ($,PI,SF,SF,SF,SF,I,I,I,I,PAL,I,PAL,I) -> Void
 ++ graphState(v,num,sX,sY,dX,dY,pts,lns,box,axes,axesC,un,unC,cP)
 ++ sets the state of the characteristics for the graph indicated
 ++ by \spad{num} in the given two-dimensional viewport v, of domain
 ++ \spadtype{TwoDimensionalViewport}, to the values given as
 ++ parameters. The scaling of the graph in the x and y component
 ++ directions is set to be \spad{sX} and \spad{sY}; the window
 ++ translation in the x and y component directions is set to be
 ++ \spad{dX} and \spad{dY}; The graph points, lines, bounding box,
 ++ axes, or units will be shown in the viewport if their given
 ++ parameters \spad{pts}, \spad{lns}, \spad{box}, \spad{axes} or
 ++ \spad{un} are set to be \spad{1}, but will not be shown if they

```

```

++ are set to \spad{0}. The color of the axes and the color of the
++ units are indicated by the palette colors \spad{axesC} and
++ \spad{unC} respectively. To display the control panel when
++ the viewport window is displayed, set \spad{cP} to \spad{1},
++ otherwise set it to \spad{0}.
graphStates : $ -> V GS
++ graphStates(v) returns and shows a listing of a record containing
++ the current state of the characteristics of each of the ten graph
++ records in the given two-dimensional viewport, v, which is of
++ domain \spadtype{TwoDimensionalViewport}.
graphs : $ -> V GU
++ graphs(v) returns a vector, or list, which is a union of all
++ the graphs, of the domain \spadtype{GraphImage}, which are
++ allocated for the two-dimensional viewport, v, of domain
++ \spadtype{TwoDimensionalViewport}. Those graphs which have
++ no data are labeled "undefined", otherwise their contents
++ are shown.
title : ($,STR) -> Void
++ title(v,s) changes the title which is shown in the two-dimensional
++ viewport window, v of domain \spadtype{TwoDimensionalViewport}.
putGraph : ($,G,PI) -> Void
++ putGraph(v,gi,n) sets the graph field indicated by n, of the
++ indicated two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, to be the graph, \spad{gi}
++ of domain \spadtype{GraphImage}. The contents of viewport, v,
++ will contain \spad{gi} when the function \spadfun{makeViewport2D}
++ is called to create the an updated viewport v.
getGraph : ($,PI) -> G
++ getGraph(v,n) returns the graph which is of the domain
++ \spadtype{GraphImage} which is located in graph field n
++ of the given two-dimensional viewport, v, which is of the
++ domain \spadtype{TwoDimensionalViewport}.
axes : ($,PI,STR) -> Void
++ axes(v,n,s) displays the axes of the graph in field n of
++ the given two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, if s is "on", or does
++ not display the axes if s is "off".
axes : ($,PI,PAL) -> Void
++ axes(v,n,c) displays the axes of the graph in field n of
++ the given two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, with the axes color set to
++ the given palette color c.
units : ($,PI,STR) -> Void
++ units(v,n,s) displays the units of the graph in field n of
++ the given two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, if s is "on", or does
++ not display the units if s is "off".
units : ($,PI,PAL) -> Void
++ units(v,n,c) displays the units of the graph in field n of
++ the given two-dimensional viewport, v, which is of domain

```

```

++ \spadtype{TwoDimensionalViewport}, with the units color set to
++ the given palette color c.
points : ($,PI,STR) -> Void
++ points(v,n,s) displays the points of the graph in field n of
++ the given two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, if s is "on", or does
++ not display the points if s is "off".
region : ($,PI,STR) -> Void
++ region(v,n,s) displays the bounding box of the graph in
++ field n of the given two-dimensional viewport, v, which is
++ of domain \spadtype{TwoDimensionalViewport}, if s is "on",
++ or does not display the bounding box if s is "off".
connect : ($,PI,STR) -> Void
++ connect(v,n,s) displays the lines connecting the graph
++ points in field n of the given two-dimensional viewport, v,
++ which is of domain \spadtype{TwoDimensionalViewport}, if s
++ is "on", or does not display the lines if s is "off".
controlPanel : ($,STR) -> Void
++ controlPanel(v,s) displays the control panel of the given
++ two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, if s is "on", or hides
++ the control panel if s is "off".
close : $ -> Void
++ close(v) closes the viewport window of the given
++ two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, and terminates the
++ corresponding process ID.
dimensions : ($,NNI,NNI,PI,PI) -> Void
++ dimensions(v,x,y,width,height) sets the position of the
++ upper left-hand corner of the two-dimensional viewport, v,
++ which is of domain \spadtype{TwoDimensionalViewport}, to
++ the window coordinate x, y, and sets the dimensions of the
++ window to that of \spad{width}, \spad{height}. The new
++ dimensions are not displayed until the function
++ \spadfun{makeViewport2D} is executed again for v.
scale : ($,PI,F,F) -> Void
++ scale(v,n,sx,sy) displays the graph in field n of the given
++ two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, scaled by the factor \spad{sx}
++ in the x-coordinate direction and by the factor \spad{sy} in
++ the y-coordinate direction.
translate : ($,PI,F,F) -> Void
++ translate(v,n,dx,dy) displays the graph in field n of the given
++ two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, translated by \spad{dx} in
++ the x-coordinate direction from the center of the viewport, and
++ by \spad{dy} in the y-coordinate direction from the center.
++ Setting \spad{dx} and \spad{dy} to \spad{0} places the center
++ of the graph at the center of the viewport.
show : ($,PI,STR) -> Void

```

```

++ show(v,n,s) displays the graph in field n of the given
++ two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, if s is "on", or does not
++ display the graph if s is "off".
move : ($,NNI,NNI) -> Void
++ move(v,x,y) displays the two-dimensional viewport, v, which
++ is of domain \spadtype{TwoDimensionalViewport}, with the upper
++ left-hand corner of the viewport window at the screen
++ coordinate position x, y.
update : ($,G,PI) -> Void
++ update(v,gr,n) drops the graph \spad{gr} in slot \spad{n}
++ of viewport \spad{v}. The graph gr must have been
++ transmitted already and acquired an integer key.
resize : ($,PI,PI) -> Void
++ resize(v,w,h) displays the two-dimensional viewport, v, which
++ is of domain \spadtype{TwoDimensionalViewport}, with a width
++ of w and a height of h, keeping the upper left-hand corner
++ position unchanged.
write : ($,STR) -> STR
++ write(v,s) takes the given two-dimensional viewport, v, which
++ is of domain \spadtype{TwoDimensionalViewport}, and creates
++ a directory indicated by s, which contains the graph data
++ files for v.
write : ($,STR,STR) -> STR
++ write(v,s,f) takes the given two-dimensional viewport, v, which
++ is of domain \spadtype{TwoDimensionalViewport}, and creates
++ a directory indicated by s, which contains the graph data
++ files for v and an optional file type f.
write : ($,STR,L STR) -> STR
++ write(v,s,lf) takes the given two-dimensional viewport, v, which
++ is of domain \spadtype{TwoDimensionalViewport}, and creates
++ a directory indicated by s, which contains the graph data
++ files for v and the optional file types indicated by the list lf.
reset : $ -> Void
++ reset(v) sets the current state of the graph characteristics
++ of the given two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, back to their initial settings.
key : $ -> I
++ key(v) returns the process ID number of the given two-dimensional
++ viewport, v, which is of domain \spadtype{TwoDimensionalViewport}.
coerce : $ -> E
++ coerce(v) returns the given two-dimensional viewport, v, which
++ is of domain \spadtype{TwoDimensionalViewport} as output of
++ the domain \spadtype{OutputForm}.

=====  
UnivariateLaurentSeries examples  
=====

UnivariateLaurentSeries is a domain representing Laurent series in one variable with coefficients in an arbitrary ring. The parameters of the type specify the coefficient ring, the power series variable, and the center of the power series expansion. For example, UnivariateLaurentSeries(Integer,x,3) represents Laurent series in  $(x - 3)$  with integer coefficients.

## — domain ULS UnivariateLaurentSeries —

```

)abbrev domain ULS UnivariateLaurentSeries
++ Author: Clifton J. Williamson
++ Date Created: 18 January 1990
++ Date Last Updated: 21 September 1993
++ Description:
++ Dense Laurent series in one variable
++ \spadtype{UnivariateLaurentSeries} is a domain representing Laurent
++ series in one variable with coefficients in an arbitrary ring. The
++ parameters of the type specify the coefficient ring, the power series
++ variable, and the center of the power series expansion. For example,
++ \spad{UnivariateLaurentSeries(Integer,x,3)} represents Laurent series in
++ \spad{(x - 3)} with integer coefficients.

UnivariateLaurentSeries(Coef,var,cen): Exports == Implementation where
 Coef : Ring
 var : Symbol
 cen : Coef
 I ==> Integer
 UTS ==> UnivariateTaylorSeries(Coef,var,cen)

Exports ==> UnivariateLaurentSeriesConstructorCategory(Coef,UTS) with
 coerce: Variable(var) -> %
 ++ \spad{coerce(var)} converts the series variable \spad{var} into a
 ++ Laurent series.
 differentiate: (%,Variable(var)) -> %
 ++ \spad{differentiate(f(x),x)} returns the derivative of
 ++ \spad{f(x)} with respect to \spad{x}.
 if Coef has Algebra Fraction Integer then
 integrate: (%,Variable(var)) -> %
 ++ \spad{integrate(f(x))} returns an anti-derivative of the power
 ++ series \spad{f(x)} with constant coefficient 0.
 ++ We may integrate a series when we can divide coefficients
 ++ by integers.

Implementation ==> UnivariateLaurentSeriesConstructor(Coef,UTS) add

 variable x == var
 center x == cen

 coerce(v:Variable(var)) ==
 zero? cen => monomial(1,1)
 monomial(1,1) + monomial(cen,0)

 differentiate(x:%,v:Variable(var)) == differentiate x

 if Coef has Algebra Fraction Integer then
 integrate(x:%,v:Variable(var)) == integrate x

=====
UnivariateLaurentSeriesConstructor examples
=====

```

This package enables one to construct a univariate Laurent series domain from a univariate Taylor series domain. Univariate Laurent series are represented by a pair  $[n, f(x)]$ , where  $n$  is an arbitrary integer and  $f(x)$  is a Taylor series. This pair represents the Laurent series  $x^{*n} * f(x)$ .

=====  
UnivariatePolynomial examples  
=====

The domain constructor UnivariatePolynomial (abbreviated UP) creates domains of univariate polynomials in a specified variable. For example, the domain UP(a1,POLY FRAC INT) provides polynomials in the single variable a1 whose coefficients are general polynomials with rational number coefficients.

Restriction: Axiom does not allow you to create types where UnivariatePolynomial is contained in the coefficient type of Polynomial. Therefore, UP(x,POLY INT) is legal but POLY UP(x,INT) is not.

UP(x,INT) is the domain of polynomials in the single variable x with integer coefficients.

```

(p,q) : UP(x,INT)
Type: Void

```

```

p := (3*x-1)**2 * (2*x + 8)
 3 2
 18x + 60x - 46x + 8
Type: UnivariatePolynomial(x,Integer)

```

```

q := (1 - 6*x + 9*x**2)**2
 4 3 2
 81x - 108x + 54x - 12x + 1
 Type: UnivariatePolynomial(x,Integer)

```

The usual arithmetic operations are available for univariate polynomials.

```

p**2 + p*q
 7 6 5 4 3 2
 1458x + 3240x - 7074x + 10584x - 9282x + 4120x - 878x + 72
 Type: UnivariatePolynomial(x,Integer)

```

The operation `leadingCoefficient` extracts the coefficient of the term of highest degree.

```

leadingCoefficient p
 18
 Type: PositiveInteger

```

The operation `degree` returns the degree of the polynomial. Since the polynomial has only one variable, the variable is not supplied to operations like `degree`.

```

degree p
 3
 Type: PositiveInteger

```

The reductum of the polynomial, the polynomial obtained by subtracting the term of highest order, is returned by `reductum`.

```

reductum p
 2
 60x - 46x + 8
 Type: UnivariatePolynomial(x,Integer)

```

The operation `gcd` computes the greatest common divisor of two polynomials.

```

gcd(p,q)
 2
 9x - 6x + 1
 Type: UnivariatePolynomial(x,Integer)

```

The operation `lcm` computes the least common multiple.

```

lcm(p,q)
 5 4 3 2
 162x + 432x - 756x + 408x - 94x + 8
 Type: UnivariatePolynomial(x,Integer)

```

The operation resultant computes the resultant of two univariate polynomials. In the case of p and q, the resultant is 0 because they share a common root.

```
resultant(p,q)
0
Type: NonNegativeInteger
```

To compute the derivative of a univariate polynomial with respect to its variable, use the function D.

```
D p
2
54x + 120x - 46
Type: UnivariatePolynomial(x,Integer)
```

Univariate polynomials can also be used as if they were functions. To evaluate a univariate polynomial at some point, apply the polynomial to the point.

```
p(2)
300
Type: PositiveInteger
```

The same syntax is used for composing two univariate polynomials, i.e. substituting one polynomial for the variable in another. This substitutes q for the variable in p.

```
p(q)
12 11 10 9 8
9565938x - 38263752x + 70150212x - 77944680x + 58852170x
+
7 6 5 4 3 2
- 32227632x + 13349448x - 4280688x + 1058184x - 192672x + 23328x
+
- 1536x + 40
Type: UnivariatePolynomial(x,Integer)
```

This substitutes p for the variable in q.

```
q(p)
12 11 10 9 8
8503056x + 113374080x + 479950272x + 404997408x - 1369516896x
+
7 6 5 4 3
- 626146848x + 2939858712x - 2780728704x + 1364312160x - 396838872x
+
2
69205896x - 6716184x + 279841
Type: UnivariatePolynomial(x,Integer)
```

To obtain a list of coefficients of the polynomial, use `coefficients`.

```
l := coefficients p
 [18,60,- 46,8]
 Type: List Integer
```

From this you can use `gcd` and `reduce` to compute the content of the polynomial.

```
reduce(gcd,l)
 2
 Type: PositiveInteger
```

Alternatively (and more easily), you can just call `content`.

```
content p
 2
 Type: PositiveInteger
```

Note that the operation `coefficients` omits the zero coefficients from the list. Sometimes it is useful to convert a univariate polynomial to a vector whose  $i$ -th position contains the degree  $i-1$  coefficient of the polynomial.

```
ux := (x**4+2*x+3)::UP(x,INT)
 4
 x + 2x + 3
 Type: UnivariatePolynomial(x,Integer)
```

To get a complete vector of coefficients, use the operation `vectorise`, which takes a univariate polynomial and an integer denoting the length of the desired vector.

```
vectorise(ux,5)
 [3,2,0,0,1]
 Type: Vector Integer
```

It is common to want to do something to every term of a polynomial, creating a new polynomial in the process.

This is a function for iterating across the terms of a polynomial, squaring each term.

```
squareTerms(p) == reduce(+,[t**2 for t in monomials p])
 Type: Void
```

Recall what `p` looked like.

```
p
 3 2
```

```
18x6 + 60x4 - 46x2 + 8
Type: UnivariatePolynomial(x,Integer)
```

We can demonstrate squareTerms on p.

```
squareTerms p
 6 4 2
324x6 + 3600x4 + 2116x2 + 64
Type: UnivariatePolynomial(x,Integer)
```

When the coefficients of the univariate polynomial belong to a field, it is possible to compute quotients and remainders. For example, when the coefficients are rational numbers, as opposed to integers. The important property of a field is that non-zero elements can be divided and produce another element. The quotient of the integers 2 and 3 is not another integer.

```
(r,s) : UP(a1,FRAC INT)
Type: Void

r := a1**2 - 2/3
 2 2
a1 - -
 3
Type: UnivariatePolynomial(a1,Fraction Integer)
```

```
s := a1 + 4
a1 + 4
Type: UnivariatePolynomial(a1,Fraction Integer)
```

When the coefficients are rational numbers or rational expressions, the operation quo computes the quotient of two polynomials.

```
r quo s
a1 - 4
Type: UnivariatePolynomial(a1,Fraction Integer)
```

The operation rem computes the remainder.

```
r rem s
46
--
3
Type: UnivariatePolynomial(a1,Fraction Integer)
```

The operation divide can be used to return a record of both components.

```
d := divide(r, s)
46
[quotient= a1 - 4,remainder= --]
```

3

```
Type: Record(quotient: UnivariatePolynomial(a1,Fraction Integer),
 remainder: UnivariatePolynomial(a1,Fraction Integer))
```

Now we check the arithmetic!

```
r - (d.quotient * s + d.remainder)
0
 Type: UnivariatePolynomial(a1,Fraction Integer)
```

It is also possible to integrate univariate polynomials when the coefficients belong to a field.

```
integrate r
1 3 2
- a1 - - a1
3 3
 Type: UnivariatePolynomial(a1,Fraction Integer)
```

```
integrate s
1 2
- a1 + 4a1
2
 Type: UnivariatePolynomial(a1,Fraction Integer)
```

One application of univariate polynomials is to see expressions in terms of a specific variable.

We start with a polynomial in  $a_1$  whose coefficients are quotients of polynomials in  $b_1$  and  $b_2$ .

```
t : UP(a1,FRAC POLY INT)
 Type: Void
```

Since in this case we are not talking about using multivariate polynomials in only two variables, we use `Polynomial`. We also use `Fraction` because we want fractions.

```
t := a1**2 - a1/b2 + (b1**2-b1)/(b2+3)
 2
2 1 b1 - b1
a1 - -- a1 + -----
b2 b2 + 3
 Type: UnivariatePolynomial(a1,Fraction Polynomial Integer)
```

We push all the variables into a single quotient of polynomials.

```
u : FRAC POLY INT := t
2 2 2 2
a1 b2 + (b1 - b1 + 3a1 - a1)b2 - 3a1
```

---

$$b2^2 + 3b2$$

Type: Fraction Polynomial Integer

Alternatively, we can view this as a polynomial in the variable This is a mode-directed conversion: you indicate as much of the structure as you care about and let Axiom decide on the full type and how to do the transformation.

u :: UP(b1,?)

$$\frac{1}{b2 + 3} b1^2 - \frac{1}{b2 + 3} b1 + \frac{a1 b2 - a1}{b2}$$

Type: UnivariatePolynomial(b1,Fraction Polynomial Integer)

## — domain UP UnivariatePolynomial —

```

)abbrev domain UP UnivariatePolynomial
++ Author: Mark Botch
++ Description:
++ This domain represents univariate polynomials in some symbol
++ over arbitrary (not necessarily commutative) coefficient rings.
++ The representation is sparse
++ in the sense that only non-zero terms are represented.
++ Note that if the coefficient ring is a field, then this domain
++ forms a euclidean domain.

UnivariatePolynomial(x:Symbol, R:Ring):
 UnivariatePolynomialCategory(R) with
 coerce: Variable(x) -> %
 ++ coerce(x) converts the variable x to a univariate polynomial.
 fmeCG: (% , NonNegativeInteger, R, %) -> %
 ++ fmeCG(p1, e, r, p2) finds x : p1 - r * x**e * p2
 == SparseUnivariatePolynomial(R) add
 Rep:=SparseUnivariatePolynomial(R)
 coerce(p:%):OutputForm == outputForm(p, outputForm x)
 coerce(v:Variable(x)):% == monomial(1, 1)

=====
UnivariatePuisseuxSeries examples
=====
```

UnivariatePuisseuxSeries is a domain representing Puiseux series in one variable with coefficients in an arbitrary ring. The parameters of the type specify the coefficient ring, the power series variable, and the center of the power series expansion. For example, `UnivariatePuisseuxSeries(Integer,x,3)` represents Puiseux series in  $(x - 3)$  with Integer coefficients.

=====

UnivariatePuisseuxSeriesConstructor examples

=====

This package enables one to construct a univariate Puiseux series domain from a univariate Laurent series domain. Univariate Puiseux series are represented by a pair  $[r, f(x)]$ , where  $r$  is a positive rational number and  $f(x)$  is a Laurent series. This pair represents the Puiseux series  $f(x^r)$ .

=====  
UnivariatePuisseuxSeriesWithExponentialSingularity examples  
=====

UnivariatePuisseuxSeriesWithExponentialSingularity is a domain used to represent functions with essential singularities. Objects in this domain are sums, where each term in the sum is a univariate Puisseux series times the exponential of a univariate Puisseux series. Thus, the elements of this domain are sums of expressions of the form  $g(x) * \exp(f(x))$ , where  $g(x)$  is a univariate Puisseux series and  $f(x)$  is a univariate Puisseux series with no terms of non-negative degree.

=====
UnivariateSkewPolynomial examples
=====

```

Skew or Ore polynomial rings provide a unified framework to compute with differential and difference equations.

In the following, let  $A$  be an integral domain, equipped with two endomorphisms  $\sigma$  and  $\delta$  where:

$\sigma: A \rightarrow A$  is an injective ring endomorphism  
 $\delta: A \rightarrow A$ , the pseudo-derivation with respect to  $\sigma$ ,  
 is an additive endomorphism with

$$\delta(ab) = \sigma(a)\delta(b) + \delta(a)b$$

for all  $a, b$  in  $A$

Note that in the domains and categories below, these properties are not checked.

The skew polynomial ring  $[\Delta; \sigma, \delta]$  is the ring of polynomials in  $\Delta$  with coefficients in  $A$ , with the usual addition, while the product is given by

$$\Delta a = \sigma(a)\Delta + \delta(a) \text{ for } a \text{ in } A$$

The two most important examples of skew polynomial rings are:

$K(x)[D, 1, \delta]$ , where  $1$  is the identity on  $K$  and  $\delta$  is the usual derivative, is the ring of differential polynomials

$K[E, n, \text{mapsto } n+1, 0]$  is the ring of linear recurrence operators with polynomial coefficients

-----  
 For example,

The `UnivariateSkewPolynomialCategory` (OREPCAT) provides a unified framework for polynomial rings in a non-central indeterminate over some coefficient ring  $R$ . The commutation relations between the indeterminate  $x$  and the coefficient  $t$  is given by

$$x r = \sigma(r) x + \delta(r)$$

where  $\sigma$  is a ring endomorphism of  $R$   
 and  $\delta$  is a  $\sigma$ -derivation of  $R$   
 which is an additive map from  $R$  to  $R$  such that

$$\delta(rs) = \sigma(r) \delta(s) + \delta(r) s$$

In case  $\sigma$  is the identity map on  $R$ , a  $\sigma$ -derivation of  $R$  is just called a derivation. Here are some examples

We start with a linear ordinary differential operator. First, we define the coefficient ring to be expressions in one variable  $x$  with fractional coefficients:

```
F:=EXPR(FRAC(INT))
```

Define  $D_x$  to be a derivative  $d/dx$ :

```
Dx:F->F:=f+-->D(f,['x])
```

Define a skew polynomial ring over  $F$  with identity endomorphism as  $\sigma$  and derivation  $d/dx$  as  $\delta$ :

```
D0:=OREUP('d,F,1,Dx)
```

```
u:D0:=(operator 'u)(x)
```

```
d:D0:='d
```

```
a:D0:=u^3*d^3+u^2*d^2+u*d+1
```

$$u(x)^3 d^3 + u(x)^2 d^2 + u(x)d + 1$$

```
b:D0:=(u+1)*d^2+2*d
```

$$(u(x) + 1)d^2 + 2d$$

```
r:=rightDivide(a,b)
```

$$[\text{quotient} = \frac{u(x)^3}{u(x) + 1} d + \frac{-u(x)^3 u(x) - u(x)^3 + u(x)^2}{u(x)^2 + 2u(x) + 1},$$

$$\frac{2u(x)^3 u(x) + 3u(x)^3 + u(x)^3}{u(x)^2 + 2u(x) + 1}]$$

$$\text{remainder} = \frac{d + 1}{u(x)^2 + 2u(x) + 1}$$

```
r.quotient
```

$$\frac{u(x)^3}{u(x)+1} d + \frac{-u(x)^3 u'(x) - u(x)^3 + u(x)^2}{u(x)^2 + 2u(x) + 1}$$

r.remainder

$$\frac{2u(x)^3 u'(x) + 3u(x)^3 + u(x)^3}{u(x)^2 + 2u(x) + 1} d + 1$$

)clear all

As a second example, we consider the so-called Weyl algebra.

Define the coefficient ring to be an ordinary polynomial over integers in one variable t

R:=UP('t,INT)

Define a skew polynomial ring over R with identity map as \sigma and derivation d/dt as \delta. The resulting algebra is then called a Weyl algebra. This is a simple ring over a division ring that is non-commutative, similar to the ring of matrices.

W:=OREUP('x,R,1,D)

t:W:='t

x:W:='x

Let

a:W:=(t-1)\*x^4+(t^3+3\*t+1)\*x^2+2\*t\*x+t^3

$$(t-1)x^4 + (t^3 + 3t + 1)x^2 + 2tx + t^3$$

b:W:=(6\*t^4+2\*t^2)\*x^3+3\*t^2\*x^2

$$(6t^4 + 2t^3)x^2 + 3t^2x^2$$

Then

a\*b

$$\begin{aligned} & (6t^5 - 6t^4 + 2t^3 - 2t^2)x^7 + (96t^4 - 93t^3 + 13t^2 - 16t)x^6 \\ & + (6t^7 + 20t^5 + 6t^4 + 438t^3 - 406t^2 - 24t)x^5 \\ & + (48t^6 + 15t^5 + 152t^4 + 61t^3 + 603t^2 - 532t - 36)x^4 \\ & + (6t^7 + 74t^5 + 60t^4 + 226t^3 + 116t^2 + 168t - 140)x^3 \\ & + (3t^5 + 6t^3 + 12t^2 + 18t + 6)x^2 \end{aligned}$$

a^3

$$\begin{aligned} & (t^3 - 3t^2 + 3t - 1)x^{12} + (3t^5 - 6t^4 + 12t^3 - 15t^2 + 3t + 3)x^{10} \\ & + (6t^3 - 12t^2 + 6t)x^9 + (3t^7 - 3t^6 + 21t^5 - 18t^4 + 24t^3 - 9t^2 - 15t - 3)x^8 \\ & + (12t^5 - 12t^4 + 36t^3 - 24t^2 - 12t)x^7 \\ & + (t^9 + 15t^7 - 3t^6 + 45t^5 + 6t^4 + 36t^3 + 15t^2 + 9t + 1)x^6 \\ & + (6t^7 + 48t^5 + 54t^3 + 36t^2 + 6t)x^5 \\ & + (3t^9 + 21t^7 + 3t^6 + 39t^5 + 18t^4 + 39t^3 + 12t^2)x^4 \\ & + (12t^7 + 36t^5 + 12t^4 + 8t^3)x^3 + (3t^9 + 9t^7 + 3t^6 + 12t^5)x^2 + 6t^2x + t^9 \end{aligned}$$

-----

)clear all

As a third example, we construct a difference operator algebra over the ring of EXPR(INT) by using an automorphism S defined by a

"shift" operation  $S: \text{EXPR}(\text{INT}) \rightarrow \text{EXPR}(\text{INT})$

$$s(e)(n) = e(n+1)$$

and an S-derivation defined by  $DF: \text{EXPR}(\text{INT}) \rightarrow \text{EXPR}(\text{INT})$  as

$$DF(e)(n) = e(n+1) - e(n)$$

Define S to be a "shift" operator, which acts on expressions with the discrete variable n:

$$S: \text{EXPR}(\text{INT}) \rightarrow \text{EXPR}(\text{INT}) := e \mapsto \text{eval}(e, [n], [n+1])$$

Define DF to be a "difference" operator, which acts on expressions with a discrete variable n:

$$DF: \text{EXPR}(\text{INT}) \rightarrow \text{EXPR}(\text{INT}) := e \mapsto \text{eval}(e, [n], [n+1]) - e$$

Then define the difference operator algebra D0:

$$D0 := \text{OREUP}('D, \text{EXPR}(\text{INT}), \text{morphism } S, DF)$$

$$u := (\text{operator } 'u)[n]$$

$$L: D0 := 'D + u$$

$$D + u(n)$$

$$L^2$$

$$D^2 + 2u(n)D + u(n)^2$$

-----  
 )clear all

As a fourth example, we construct a skew polynomial ring by using an inner derivation  $\delta$  induced by a fixed  $y$  in  $R$ :

$$\delta(r) = yr - ry$$

First we should expose the constructor SquareMatrix so it is visible in the interpreter:

)set expose add constructor SquareMatrix

Define R to be the square matrix with integer entries:

$$R := \text{SQMATRIX}(2, \text{INT})$$

```

y:R:=matrix [[1,1],[0,1]]
 +1 1+
 | |
 +0 1+

```

Define the inner derivative  $\delta$ :

```
delta:R->R:=r+>y*r-r*y
```

Define  $S$  to be a skew polynomial determined by  $\sigma = 1$  and  $\delta$  as an inner derivative:

```
S:=OREUP('x,R,1,delta)
```

```
x:S:='x
```

```

a:S:=matrix [[2,3],[1,1]]
 +2 3+
 | |
 +1 1+

```

```

x^2*a
 +2 3+ 2 +2 - 2+ +0 - 2+
 | |x + | |x + | |
 +1 1+ +0 - 2+ +0 0 +

```

=====  
UnivariateTaylorSeries examples  
=====

Dense Taylor series in one variable. `UnivariateTaylorSeries` is a domain representing Taylor series in one variable with coefficients in an arbitrary ring. The parameters of the type specify the coefficient ring, the power series variable, and the center of the power series expansion. For example, `UnivariateTaylorSeries(Integer,x,3)` represents Taylor series in  $(x - 3)$  with Integer coefficients.

## — domain UTS UnivariateTaylorSeries —

```
)abbrev domain UTS UnivariateTaylorSeries
++ Author: Clifton J. Williamson
++ Date Created: 21 December 1989
++ Date Last Updated: 21 September 1993
++ Description:
++ Dense Taylor series in one variable
++ \spadtype{UnivariateTaylorSeries} is a domain representing Taylor
++ series in
++ one variable with coefficients in an arbitrary ring. The parameters
++ of the type specify the coefficient ring, the power series variable,
++ and the center of the power series expansion. For example,
++ \spadtype{UnivariateTaylorSeries}(Integer,x,3) represents
++ Taylor series in
++ \spad{(x - 3)} with \spadtype{Integer} coefficients.
```

```
UnivariateTaylorSeries(Coef,var,cen): Exports == Implementation where
 Coef : Ring
 var : Symbol
 cen : Coef
 I ==> Integer
 NNI ==> NonNegativeInteger
```

```

P ==> Polynomial Coef
RN ==> Fraction Integer
ST ==> Stream
STT ==> StreamTaylorSeriesOperations Coef
TERM ==> Record(k:NNI,c:Coef)
UP ==> UnivariatePolynomial(var,Coef)
Exports ==> UnivariateTaylorSeriesCategory(Coef) with
 coerce: UP -> %
 ++\spad{coerce(p)} converts a univariate polynomial p in the variable
 ++\spad{var} to a univariate Taylor series in \spad{var}.
 univariatePolynomial: (% ,NNI) -> UP
 ++\spad{univariatePolynomial(f,k)} returns a univariate polynomial
 ++ consisting of the sum of all terms of f of degree \spad{<= k}.
 coerce: Variable(var) -> %
 ++\spad{coerce(var)} converts the series variable \spad{var} into a
 ++ Taylor series.
 differentiate: (% ,Variable(var)) -> %
 ++ \spad{differentiate(f(x),x)} computes the derivative of
 ++ \spad{f(x)} with respect to \spad{x}.
 lagrange: % -> %
 ++\spad{lagrange(g(x))} produces the Taylor series for \spad{f(x)}
 ++ where \spad{f(x)} is implicitly defined as \spad{f(x) = x*g(f(x))}.
 lambert: % -> %
 ++\spad{lambert(f(x))} returns \spad{f(x) + f(x^2) + f(x^3) + ...}.
 ++ This function is used for computing infinite products.
 ++ \spad{f(x)} should have zero constant coefficient.
 ++ If \spad{f(x)} is a Taylor series with constant term 1, then
 ++ \spad{product(n = 1..infinity,f(x^n)) = exp(log(lambert(f(x))))}.
 oddlambert: % -> %
 ++\spad{oddlambert(f(x))} returns \spad{f(x) + f(x^3) + f(x^5) + ...}.
 ++ \spad{f(x)} should have a zero constant coefficient.
 ++ This function is used for computing infinite products.
 ++ If \spad{f(x)} is a Taylor series with constant term 1, then
 ++ \spad{product(n=1..infinity,f(x^(2*n-1)))=exp(log(oddlambert(f(x))))}.
 evenlambert: % -> %
 ++\spad{evenlambert(f(x))} returns \spad{f(x^2) + f(x^4) + f(x^6) + ...}.
 ++ \spad{f(x)} should have a zero constant coefficient.
 ++ This function is used for computing infinite products.
 ++ If \spad{f(x)} is a Taylor series with constant term 1, then
 ++ \spad{product(n=1..infinity,f(x^(2*n))) = exp(log(evenlambert(f(x))))}.
 generalLambert: (% ,I,I) -> %
 ++\spad{generalLambert(f(x),a,d)} returns \spad{f(x^a) + f(x^(a + d)) +
 ++ f(x^(a + 2 d)) + ... }. \spad{f(x)} should have zero constant
 ++ coefficient and \spad{a} and d should be positive.
 revert: % -> %
 ++ \spad{revert(f(x))} returns a Taylor series \spad{g(x)} such that
 ++ \spad{f(g(x)) = g(f(x)) = x}. Series \spad{f(x)} should have constant
 ++ coefficient 0 and 1st order coefficient 1.
 multisect: (I,I,%) -> %
 ++\spad{multisect(a,b,f(x))} selects the coefficients of

```

```

 ++ \spad{x^((a+b)*n+a)}, and changes this monomial to \spad{x^n}.
invmultisect: (I,I,%) -> %
 ++\spad{invmultisect(a,b,f(x))} substitutes \spad{x^((a+b)*n)}
 ++ for \spad{x^n} and multiples by \spad{x^b}.
if Coef has Algebra Fraction Integer then
 integrate: (% ,Variable(var)) -> %
 ++ \spad{integrate(f(x),x)} returns an anti-derivative of the power
 ++ series \spad{f(x)} with constant coefficient 0.
 ++ We may integrate a series when we can divide coefficients
 ++ by integers.

 UP ==> UnivariatePolynomial(var,Coef)
Exports ==> UnivariateTaylorSeriesCategory(Coef) with
 coerce: UP -> %
 ++\spad{coerce(p)} converts a univariate polynomial p in the variable
 ++\spad{var} to a univariate Taylor series in \spad{var}.
 univariatePolynomial: (% ,NNI) -> UP
 ++\spad{univariatePolynomial(f,k)} returns a univariate polynomial
 ++ consisting of the sum of all terms of f of degree \spad{<= k}.
 coerce: Variable(var) -> %
 ++\spad{coerce(var)} converts the series variable \spad{var} into a
 ++ Taylor series.
 differentiate: (% ,Variable(var)) -> %
 ++ \spad{differentiate(f(x),x)} computes the derivative of
 ++ \spad{f(x)} with respect to \spad{x}.
 lagrange: % -> %
 ++\spad{lagrange(g(x))} produces the Taylor series for \spad{f(x)}
 ++ where \spad{f(x)} is implicitly defined as \spad{f(x) = x*g(f(x))}.
 lambert: % -> %
 ++\spad{lambert(f(x))} returns \spad{f(x) + f(x^2) + f(x^3) + ...}.
 ++ This function is used for computing infinite products.
 ++ \spad{f(x)} should have zero constant coefficient.
 ++ If \spad{f(x)} is a Taylor series with constant term 1, then
 ++ \spad{product(n = 1..infinity,f(x^n)) = exp(log(lambert(f(x))))}.
 oddlambert: % -> %
 ++\spad{oddlambert(f(x))} returns \spad{f(x) + f(x^3) + f(x^5) + ...}.
 ++ \spad{f(x)} should have a zero constant coefficient.
 ++ This function is used for computing infinite products.
 ++ If \spad{f(x)} is a Taylor series with constant term 1, then
 ++ \spad{product(n=1..infinity,f(x^(2*n-1)))=exp(log(oddlambert(f(x))))}.
 evenlambert: % -> %
 ++\spad{evenlambert(f(x))} returns \spad{f(x^2) + f(x^4) + f(x^6) + ...}.
 ++ \spad{f(x)} should have a zero constant coefficient.
 ++ This function is used for computing infinite products.

```

```

++ If \spad{f(x)} is a Taylor series with constant term 1, then
++ \spad{product(n=1..infinity,f(x^(2*n)))=exp(log(evenlambert(f(x))))}.
generalLambert: (% ,I,I) -> %
++\spad{generalLambert(f(x),a,d)} returns \spad{f(x^a) + f(x^(a + d)) +
++ f(x^(a + 2 d)) + ... }. \spad{f(x)} should have zero constant
++ coefficient and \spad{a} and d should be positive.
revert: % -> %
++ \spad{revert(f(x))} returns a Taylor series \spad{g(x)} such that
++ \spad{f(g(x)) = g(f(x)) = x}. Series \spad{f(x)} should have constant
++ coefficient 0 and 1st order coefficient 1.
multisect: (I,I,%) -> %
++\spad{multisect(a,b,f(x))} selects the coefficients of
++ \spad{x^((a+b)*n+a)}, and changes this monomial to \spad{x^n}.
invmultisect: (I,I,%) -> %
++\spad{invmultisect(a,b,f(x))} substitutes \spad{x^((a+b)*n)}
++ for \spad{x^n} and multiples by \spad{x^b}.
if Coef has Algebra Fraction Integer then
integrate: (% ,Variable(var)) -> %
++ \spad{integrate(f(x),x)} returns an anti-derivative of the power
++ series \spad{f(x)} with constant coefficient 0.
++ We may integrate a series when we can divide coefficients
++ by integers.

— UniversalSegment.help —

```

=====
UniversalSegment examples
=====

```

The UniversalSegment domain generalizes Segment by allowing segments without a "hi" end point.

```

pints := 1..
 1..
 Type: UniversalSegment PositiveInteger

```

```

nevns := (0..) by -2
 0.. by - 2
 Type: UniversalSegment NonNegativeInteger

```

Values of type Segment are automatically converted to type UniversalSegment when appropriate.

```

useg: UniversalSegment(Integer) := 3..10
 3..10
 Type: UniversalSegment Integer

```

The operation hasHi is used to test whether a segment has a hi end point.

```

hasHi pints
 false
 Type: Boolean

```

```

hasHi nevns
 false
 Type: Boolean

```

```
hasHi useg
true
```

Type: Boolean

All operations available on type Segment apply to UniversalSegment, with the proviso that expansions produce streams rather than lists. This is to accommodate infinite expansions.

```
expand pints
[1,2,3,4,5,6,7,8,9,10,...]
```

Type: Stream Integer

```
expand nevens
[0,- 2,- 4,- 6,- 8,- 10,- 12,- 14,- 16,- 18,...]
```

Type: Stream Integer

```
expand [1, 3, 10..15, 100..]
[1,3,10,11,12,13,14,15,100,101,...]
```

Type: Stream Integer

)abbrev domain UNISEG UniversalSegment
++ Author: Robert S. Sutor
++ Date Created: 1987
++ Date Last Updated: June 4, 1991
++ Description:
++ This domain provides segments which may be half open.
++ That is, ranges of the form \spad{a..} or \spad{a..b}.

UniversalSegment(S: Type): SegmentCategory(S) with
 SEGMENT: S -> %
 ++ \spad{1..} produces a half open segment,
 ++ that is, one with no upper bound.
 segment: S -> %
 ++ segment(1) is an alternate way to construct the segment \spad{1..}.
 coerce : Segment S -> %
 ++ coerce(x) allows \spadtype{Segment} values to be used as %.
 hasHi: % -> Boolean
 ++ hasHi(s) tests whether the segment s has an upper bound.

 if S has SetCategory then SetCategory

 if S has OrderedRing then

=====
Vector examples
=====

```

The Vector domain is used for storing data in a one-dimensional indexed data structure. A vector is a homogeneous data structure in that all the components of the vector must belong to the same Axiom domain. Each vector has a fixed length specified by the user; vectors are not extensible. This domain is similar to the OneDimensionalArray domain, except that when the components of a Vector belong to a Ring, arithmetic operations are provided.

As with the OneDimensionalArray domain, a Vector can be created by calling the operation `new`, its components can be accessed by calling the operations `elt` and `qelt`, and its components can be reset by calling the operations `setelt` and `qsetelt`.

This creates a vector of integers of length 5 all of whose components are 12.

```

u : VECTOR INT := new(5,12)
 [12,12,12,12,12]
 Type: Vector Integer

```

This is how you create a vector from a list of its components.

```

v : VECTOR INT := vector([1,2,3,4,5])
 [1,2,3,4,5]
 Type: Vector Integer

```

Indexing for vectors begins at 1. The last element has index equal to the length of the vector, which is computed by `#`.

```

#(v)

```

5

Type: PositiveInteger

This is the standard way to use `elt` to extract an element. Functionally, it is the same as if you had typed `elt(v,2)`.

```
v.2
 2
```

Type: PositiveInteger

This is the standard way to use `setelt` to change an element. It is the same as if you had typed `setelt(v,3,99)`.

```
v.3 := 99
 99
```

Type: PositiveInteger

Now look at `v` to see the change. You can use `qelt` and `qsetelt` (instead of `elt` and `setelt`, respectively) but only when you know that the index is within the valid range.

```
v
[1,2,99,4,5]
```

Type: Vector Integer

When the components belong to a Ring, Axiom provides arithmetic operations for Vector. These include left and right scalar multiplication.

```
5 * v
[5,10,495,20,25]
```

Type: Vector Integer

```
v * 7
[7,14,693,28,35]
```

Type: Vector Integer

```
w : VECTOR INT := vector([2,3,4,5,6])
[2,3,4,5,6]
```

Type: Vector Integer

Addition and subtraction are also available.

```
v + w
[3,5,103,9,11]
```

Type: Vector Integer

Of course, when adding or subtracting, the two vectors must have the same length or an error message is displayed.

```
v - w
```

[- 1,- 1,95,- 1,- 1]

Type: Vector Integer

=====
Void examples
=====

```

When an expression is not in a value context, it is given type Void.  
For example, in the expression

```

r := (a; b; if c then d else e; f)

```

values are used only from the subexpressions c and f: all others are thrown away. The subexpressions a, b, d and e are evaluated for side-effects only and have type Void. There is a unique value of type Void.

You will most often see results of type Void when you declare a variable.

```

a : Integer
 Type: Void

```

Usually no output is displayed for Void results. You can force the display of a rather ugly object by issuing

```

)set message void on

b : Fraction Integer
 Type: Void

```

```

)set message void off

```

All values can be converted to type Void.

```

3::Void
 Type: Void

```

Once a value has been converted to Void, it cannot be recovered.

```
% :: PositiveInteger
 Cannot convert from type Void to PositiveInteger for value "()"
```

=====
WuWenTsunTriangularSet examples
=====

```

The WuWenTsunTriangularSet domain constructor implements the characteristic set method of Wu Wen Tsun. This algorithm computes a list of triangular sets from a list of polynomials such that the algebraic variety defined by the given list of polynomials decomposes into the union of the regular-zero sets of the computed triangular sets. The constructor takes four arguments. The first one, R, is the coefficient ring of the polynomials; it must belong to the category IntegralDomain. The second one, E, is the exponent monoid of the polynomials; it must belong to the category OrderedAbelianMonoidSup. The third one, V, is the ordered set of variables; it must belong to the category OrderedSet. The last one is the polynomial ring; it must belong to the category RecursivePolynomialCategory(R,E,V). The abbreviation for WuWenTsunTriangularSet is WUTSET.

Let us illustrate the facilities by an example.

Define the coefficient ring.

```

R := Integer
Integer
 Type: Domain

```

Define the list of variables,

```

ls : List Symbol := [x,y,z,t]
 [x,y,z,t]
 Type: List Symbol

```

and make it an ordered set;

```

V := OVAR(ls)
 OrderedVariableList [x,y,z,t]
 Type: Domain

```

then define the exponent monoid.

```

E := IndexedExponents V
 IndexedExponents OrderedVariableList [x,y,z,t]
 Type: Domain

```

Define the polynomial ring.

```

P := NSMP(R, V)
 NewSparseMultivariatePolynomial(Integer,OrderedVariableList [x,y,z,t])
 Type: Domain

```

Let the variables be polynomial.

```

x: P := 'x
 x
 Type: NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t])

```

```

y: P := 'y
 y
 Type: NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t])

```

```

z: P := 'z
 z
 Type: NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t])

```

```

t: P := 't
 t
 Type: NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t])

```

Now call the WuWenTsunTriangularSet domain constructor.

```

T := WUTSET(R,E,V,P)
 WuWenTsunTriangularSet(Integer,IndexedExponents OrderedVariableList [x,y,z,t]
 ,OrderedVariableList [x,y,z,t],NewSparseMultivariatePolynomial(Integer,Ordere

```

```
dVariableList [x,y,z,t]))
```

```
Type: Domain
```

Define a polynomial system.

```
p1 := x ** 31 - x ** 6 - x - y
 31 6
 x - x - x - y
```

```
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])
```

```
p2 := x ** 8 - z
 8
 x - z
```

```
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])
```

```
p3 := x ** 10 - t
 10
 x - t
```

```
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])
```

```
lp := [p1, p2, p3]
```

```
 31 6 8 10
[x - x - x - y, x - z, x - t]
```

```
Type: List NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])
```

Compute a characteristic set of the system.

```
characteristicSet(lp)$T
```

```
 5 4 4 2 2 3 4 7 4 6 6 3 3 3 3
{z - t , t z y + 2t z y + (- t + 2t - t)z + t z, (t - 1)z x - z y - t }
```

```
Type: Union(WuWenTsunTriangularSet(Integer,
IndexedExponents OrderedVariableList [x,y,z,t],
OrderedVariableList [x,y,z,t],
NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])),...)
```

Solve the system.

```
zeroSetSplit(lp)$T
```

```
 3 5 4 3 3 2
[{t,z,y,x}, {t - 1, z - t , z y + t , z x - t},
```

```
 5 4 4 2 2 3 4 7 4 6 6 3 3 3 3
{z - t , t z y + 2t z y + (- t + 2t - t)z + t z, (t - 1)z x - z y - t }]
```

```
Type: List WuWenTsunTriangularSet(Integer,
IndexedExponents OrderedVariableList [x,y,z,t],
OrderedVariableList [x,y,z,t],
```

```
NewSparseMultivariatePolynomial(Integer,
 OrderedVariableList [x,y,z,t])
```

The RegularTriangularSet and SquareFreeRegularTriangularSet domain constructors, the LazardSetSolvingPackage package constructors as well as, SquareFreeRegularTriangularSet and ZeroDimensionalSolvePackage package constructors also provide operations to compute triangular decompositions of algebraic varieties. These five constructor use a special kind of characteristic sets, called regular triangular sets. These special characteristic sets have better properties than the general ones. Regular triangular sets and their related concepts are presented in the paper "On the Theories of Triangular sets" By P. Aubry, D. Lazard and M. Moreno Maza (to appear in the Journal of Symbolic Computation). The decomposition algorithm (due to the third author) available in the four above constructors provide generally better timings than the characteristic set method. In fact, the WUTSET constructor remains interesting for the purpose of manipulating characteristic sets whereas the other constructors are more convenient for solving polynomial systems.

Note that the way of understanding triangular decompositions is detailed in the example of the RegularTriangularSet constructor.

— domain WUTSET WuWenTsunTriangularSet —

)abbrev domain WUTSET WuWenTsunTriangularSet

```

++ Author: Marc Moreno Maza (marc@nag.co.uk)
++ Date Created: 11/18/1995
++ Date Last Updated: 12/15/1998
++ References :
++ [1] W. T. WU "A Zero Structure Theorem for polynomial equations solving"
++ MM Research Preprints, 1987.
++ [2] D. M. WANG "An implementation of the characteristic set method in Maple"
++ Proc. DISCO'92. Bath, England.
++ Description:
++ A domain constructor of the category \axiomType{GeneralTriangularSet}.
++ The only requirement for a list of polynomials to be a member of such
++ a domain is the following: no polynomial is constant and two distinct
++ polynomials have distinct main variables. Such a triangular set may
++ not be auto-reduced or consistent. The construct operation
++ does not check the previous requirement. Triangular sets are stored
++ as sorted lists w.r.t. the main variables of their members.
++ Furthermore, this domain exports operations dealing with the
++ characteristic set method of Wu Wen Tsun and some optimizations
++ mainly proposed by Dong Ming Wang.

Exports == TriangularSetCategory(R,E,V,P) with

```

```

medialSet : (LP,((P,P)->B),((P,P)->P)) -> Union($,"failed")
++ \axiom{medialSet(ps,redOp?,redOp)} returns \axiom{bs} a basic set
++ (in Wu Wen Tsun sense w.r.t the reduction-test \axiom{redOp?})
++ of some set generating the same ideal as \axiom{ps} (with
++ rank not higher than any basic set of \axiom{ps}), if no non-zero
++ constant polynomials appear during the computations, else
++ \axiom{"failed"} is returned. In the former case, \axiom{bs} has to be

```

```

++ understood as a candidate for being a characteristic set of \axiom{ps}.
++ In the original algorithm, \axiom{bs} is simply a basic set of \axiom{ps}.
medialSet: LP -> Union($,"failed")
++ \axiom{medial(ps)} returns the same as
++ \axiom{medialSet(ps,initiallyReduced?,initiallyReduce)}.
characteristicSet : (LP,((P,P)->B),((P,P)->P)) -> Union($,"failed")
++ \axiom{characteristicSet(ps,redOp?,redOp)} returns a non-contradictory
++ characteristic set of \axiom{ps} in Wu Wen Tsun sense w.r.t the
++ reduction-test \axiom{redOp?} (using \axiom{redOp} to reduce
++ polynomials w.r.t a \axiom{redOp?} basic set), if no
++ non-zero constant polynomial appear during those reductions,
++ else \axiom{"failed"} is returned.
++ The operations \axiom{redOp} and \axiom{redOp?} must satisfy
++ the following conditions: \axiom{redOp?(redOp(p,q),q)} holds
++ for every polynomials \axiom{p,q} and there exists an integer
++ \axiom{e} and a polynomial \axiom{f} such that we have
++ \axiom{init(q)^e*p = f*q + redOp(p,q)}.
characteristicSet: LP -> Union($,"failed")
++ \axiom{characteristicSet(ps)} returns the same as
++ \axiom{characteristicSet(ps,initiallyReduced?,initiallyReduce)}.
characteristicSerie : (LP,((P,P)->B),((P,P)->P)) -> List $
++ \axiom{characteristicSerie(ps,redOp?,redOp)} returns a list \axiom{lts}
++ of triangular sets such that the zero set of \axiom{ps} is the
++ union of the regular zero sets of the members of \axiom{lts}.
++ This is made by the Ritt and Wu Wen Tsun process applying
++ the operation \axiom{characteristicSet(ps,redOp?,redOp)}
++ to compute characteristic sets in Wu Wen Tsun sense.
characteristicSerie: LP -> List $
++ \axiom{characteristicSerie(ps)} returns the same as
++ \axiom{characteristicSerie(ps,initiallyReduced?,initiallyReduce)}.

## Chapter 25

# Chapter X

### domain XDPOLY XDistributedPolynomial

Polynomial arithmetic with non-commutative variables has been improved by a contribution of Michel Petitot (University of Lille I, France). The domain constructor **XDistributedPolynomial** provide a distributed representation for these polynomials. It is the non-commutative equivalent for the **DistributedMultivariatePolynomial** constructor.

=====
XPolynomial examples
=====
```

The XPolynomial domain constructor implements multivariate polynomials whose set of variables is Symbol. These variables do not commute. The only parameter of this constructor is the coefficient ring which may be non-commutative. However, coefficients and variables commute. The representation of the polynomials is recursive. The abbreviation for XPolynomial is XPOLY.

Other constructors like XPolynomialRing, XRecursivePolynomial as well as XDistributedPolynomial, LiePolynomial and XPBWPolynomial implement multivariate polynomials in non-commutative variables.

We illustrate now some of the facilities of the XPOLY domain constructor.

Define a polynomial ring over the integers.

```
poly := XPolynomial(Integer)
 XPolynomial Integer
 Type: Domain
```

Define a first polynomial,

```
pr: poly := 2*x + 3*y-5
 - 5 + x 2 + y 3
 Type: XPolynomial Integer
```

and a second one.

```
pr2: poly := pr*pr
 25 + x(- 20 + x 4 + y 6) + y(- 30 + x 6 + y 9)
 Type: XPolynomial Integer
```

Rewrite pr in a distributive way,

```
pd := expand pr
 - 5 + 2x + 3y
 Type: XDistributedPolynomial(Symbol,Integer)
```

compute its square,

```
pd2 := pd*pd
 25 - 20x - 30y + 4x2 + 6x y + 6y x + 9y2
 Type: XDistributedPolynomial(Symbol,Integer)
```

and checks that:

```
expand(pr2) - pd2
0
Type: XDistributedPolynomial(Symbol,Integer)
```

We define:

```
qr := pr**3
- 125 + x(150 + x(- 60 + x 8 + y 12) + y(- 90 + x 12 + y 18))
+
y(225 + x(- 90 + x 12 + y 18) + y(- 135 + x 18 + y 27))
Type: XPolynomial Integer
```

and:

```
qd := pd**3
- 125 + 150x + 225y - 60x2 - 90x y - 90y x - 135y2 + 8x3 + 12x2 y + 12x y x2
+
18x y2 + 12y x2 + 18y x y + 18y x2 + 27y3
Type: XDistributedPolynomial(Symbol,Integer)
```

We truncate qd at degree 3.

```
trunc(qd,2)
- 125 + 150x + 225y - 60x2 - 90x y - 90y x - 135y2
Type: XDistributedPolynomial(Symbol,Integer)
```

The same for qr:

```
trunc(qr,2)
- 125 + x(150 + x(- 60) + y(- 90)) + y(225 + x(- 90) + y(- 135))
Type: XPolynomial Integer
```

We define:

```
Word := OrderedFreeMonoid Symbol
OrderedFreeMonoid Symbol
Type: Domain
```

and:

```
w: Word := x*y**2
2
x y
Type: OrderedFreeMonoid Symbol
```

We can compute the right-quotient of qr by r:

```
rquo(qr,w)
18
```

Type: XPolynomial Integer

and the shuffle-product of pr by r:

```
sh(pr,w::poly)
x(x y y 4 + y(x y 2 + y(- 5 + x 2 + y 9))) + y x y y 3
Type: XPolynomial Integer
```

=====
XPolynomialRing examples
=====

```

The XPolynomialRing domain constructor implements generalized polynomials with coefficients from an arbitrary Ring (not necessarily commutative) and whose exponents are words from an arbitrary OrderedMonoid (not necessarily commutative too). Thus these polynomials are (finite) linear combinations of words.

This constructor takes two arguments. The first one is a Ring and the second is an OrderedMonoid. The abbreviation for XPolynomialRing is XPR.

Other constructors like XPolynomial, XRecursivePolynomial, XDistributedPolynomial, LiePolynomial and XPBWPolynomial implement multivariate polynomials in non-commutative variables.

We illustrate now some of the facilities of the XPR domain constructor.

Define the free ordered monoid generated by the symbols.

```

Word := OrderedFreeMonoid(Symbol)
 OrderedFreeMonoid Symbol
 Type: Domain

```

Define the linear combinations of these words with integer coefficients.

```

poly:= XPR(Integer,Word)
 XPolynomialRing(Integer,OrderedFreeMonoid Symbol)
 Type: Domain

```

Then we define a first element from poly.

```

p:poly := 2 * x - 3 * y + 1
 1 + 2x - 3y
 Type: XPolynomialRing(Integer,OrderedFreeMonoid Symbol)

```

And a second one.

```

q:poly := 2 * x + 1
 1 + 2x
 Type: XPolynomialRing(Integer,OrderedFreeMonoid Symbol)

```

We compute their sum,

```

p + q
 2 + 4x - 3y
 Type: XPolynomialRing(Integer,OrderedFreeMonoid Symbol)

```

their product,

```

p * q
 2
 1 + 4x - 3y + 4x - 6y x
 Type: XPolynomialRing(Integer,OrderedFreeMonoid Symbol)

```

and see that variables do not commute.

```

(p+q)**2-p**2-q**2-2*p*q
 - 6x y + 6y x
 Type: XPolynomialRing(Integer,OrderedFreeMonoid Symbol)

```

Now we define a ring of square matrices,

```

M := SquareMatrix(2,Fraction Integer)
 SquareMatrix(2,Fraction Integer)
 Type: Domain

```

and the linear combinations of words with these matrices as coefficients.

```

poly1:= XPR(M,Word)

```

```

XPolynomialRing(SquareMatrix(2,Fraction Integer),OrderedFreeMonoid Symbol)
Type: Domain

```

Define a first matrix,

```

m1:M := matrix [[i*j**2 for i in 1..2] for j in 1..2]
 +1 2+
 | |
 +4 8+
Type: SquareMatrix(2,Fraction Integer)

```

a second one,

```

m2:M := m1 - 5/4
 + 1 +
 |- - 2 |

)abbrev domain XPR XPolynomialRing
++ Author: Michel Petitot petitot@lifl.fr
++ Date Created: 91
++ Date Last Updated: 7 Juillet 92
++ Description:
++ This domain represents generalized polynomials with coefficients
++ (from a not necessarily commutative ring), and words
++ belonging to an arbitrary \spadtype{OrderedMonoid}.
++ This type is used, for instance, by the \spadtype{XDistributedPolynomial}
++ domain constructor where the Monoid is free.

XPolynomialRing(R:Ring,E:OrderedMonoid): T == C where
 TERM ==> Record(k: E, c: R)
 EX ==> OutputForm
 NNI ==> NonNegativeInteger

T == Join(Ring, XAlgebra(R), FreeModuleCat(R,E)) with
--operations
 "*": (% ,R) -> %
 ++ \spad{p*r} returns the product of \spad{p} by \spad{r}.
 "#": % -> NonNegativeInteger
 ++ \spad{# p} returns the number of terms in \spad{p}.
 coerce: E -> %
 ++ \spad{coerce(e)} returns \spad{1*e}
 maxdeg: % -> E
 ++ \spad{maxdeg(p)} returns the greatest word occurring in the polynomial \spad{p}
 ++ with a non-zero coefficient. An error is produced if \spad{p} is zero.
 mindeg: % -> E
 ++ \spad{mindeg(p)} returns the smallest word occurring in the polynomial \spad{p}
 ++ with a non-zero coefficient. An error is produced if \spad{p} is zero.
 reductum : % -> %
 ++ \spad{reductum(p)} returns \spad{p} minus its leading term.
 ++ An error is produced if \spad{p} is zero.
 coef : (% ,E) -> R
 ++ \spad{coef(p,e)} extracts the coefficient of the monomial \spad{e}.
 ++ Returns zero if \spad{e} is not present.
 constant?:% -> Boolean
 ++ \spad{constant?(p)} tests whether the polynomial \spad{p} belongs to the
 ++ coefficient ring.
 constant: % -> R
 ++ \spad{constant(p)} return the constant term of \spad{p}.
 quasiRegular? : % -> Boolean
 ++ \spad{quasiRegular?(x)} return true if \spad{constant(p)} is zero.
 quasiRegular : % -> %
 ++ \spad{quasiRegular(x)} return \spad{x} minus its constant term.
 map : (R -> R, %) -> %
 ++ \spad{map(fn,x)} returns \spad{Sum(fn(r_i) w_i)} if \spad{x} writes \spad{Sum(r_i w_i)}.
 if R has Field then "/" : (% ,R) -> %
 ++ \spad{p/r} returns \spad{p*(1/r)}.

=====
XRecursivePolynomial examples
=====

```

This type supports multivariate polynomials whose variables do not commute. The representation is recursive. The coefficient ring may be non-commutative. Coefficients and variables commute.

See Also:

o )show XRecursivePolynomial

---

Polynomial arithmetic with non-commutative variables has been improved by a contribution of Michel Petitot (University of Lille I, France). The domain constructors **XRecursivePolynomial** provides a recursive for these polynomials. It is the non-commutative equivalents for the **SparseMultivariatePolynomial** constructor.

## ILIST.lsp BOOTSTRAP

**ILIST** depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **ILIST** category which we can write into the **MID** directory. We compile the lisp code and copy the **ILIST.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

## INT.lsp BOOTSTRAP

**INT** depends on **OINTDOM** which depends on **ORDRING** which depends on **INT**. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **INT** category which we can write into the **MID** directory. We compile the lisp code and copy the **INT.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

---

## ISTRING.lsp BOOTSTRAP

**ISTRING** depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **ISTRING** category which we can write into the **MID** directory. We compile the lisp code and copy the **ISTRING.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

## LIST.lsp BOOTSTRAP

**LIST** depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **LIST** category which we can write into the **MID** directory. We compile the lisp code and copy the **LIST.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

## NNI.lsp BOOTSTRAP

NNI depends on itself. We need to break this cycle to build the algebra. So we keep a cached copy of the translated NNI category which we can write into the **MID** directory. We compile the lisp code and copy the **NNI.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

## PRIMARR.lsp BOOTSTRAP

**PRIMARR** depends on itself. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **PRIMARR** category which we can write into the **MID** directory. We compile the lisp code and copy the **PRIMARR.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

## SYMBOL.lsp BOOTSTRAP

**SYMBOL** depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **SYMBOL** category which we can write into the **MID** directory. We compile the lisp code and copy the **SYMBOL.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

### — SYMBOL.lsp BOOTSTRAP —

## VECTOR.lsp BOOTSTRAP

**VECTOR** depends on itself. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **VECTOR** category which we can write into the **MID** directory. We compile the lisp code and copy the **VECTOR.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.
