On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry  $IFAIL = 0$  or  $-1$ , explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry  $NGX < 3$ ,

or  $NGY < 3$ ,

or LDA is too small,

or  $ACC < 0.0$ ,

or  $MAXIT < 0$ ,

or  $IOUT < 0$ ,

or  $IOUT > 8$ .

IFAIL= 2

MAXIT iterations have been performed with the residual 2-norm decreasing at each iteration but the residual 2-norm has not been reduced to less than the specified tolerance (see ACC). Examine the progress of the iteration by setting  $IOUT \geq 2$ .

IFAIL= 3

As for IFAIL = 2, except that at one or more iterations the residual 2-norm did not decrease. It is likely that the method fails to converge for the given matrix A.

IFAIL= 4

On entry ACC is less than the machine precision. The routine terminated because the residual norm is less than the machine precision.

## 7. Accuracy

See ACC (Section 5).

## 8. Further Comments

The rate of convergence of this routine is strongly dependent upon the number of levels,  $l$ , in the multigrid scheme, and thus the choice of NGX and NGY is very important. The user is advised to experiment with different values of NGX and NGY to see the effect they have on the rate of convergence; for example, using a value such as  $NGX = 65$  (=2 +1) followed by  $NGX = 64$  (for which  $l = 1$ ).

## 9. Example

The program solves the elliptic partial differential equation

$$U_{xx} - (\alpha)U_{xy} + U_{yy} = -4, \quad (\alpha)=1.7$$

on the unit square  $0 \leq x, y \leq 1$ , with boundary conditions

$$\begin{aligned} & \{x=0, (0 \leq y \leq 1) \\ U=0 & \text{ on } \{y=0, (0 \leq x \leq 1) \cup \{y=1, (0 \leq x \leq 1) \\ & U=1 \text{ on } x=1, \quad 0 \leq y \leq 1. \end{aligned}$$

For the equation to be elliptic,  $(\alpha)$  must be less than 2.

The equation is discretized on a square grid with mesh spacing  $h$  in both directions using the following approximations:

Please see figure in printed Reference Manual

$$U_{xx} \approx \frac{1}{2h^2} (U_{E} - 2U_0 + U_{W})$$

$$U_{yy} \approx \frac{1}{2h^2} (U_{N} - 2U_0 + U_{S})$$

$$U_{xy} \approx \frac{1}{2h^2} (U_{NW} - U_{NE} - U_{SW} + U_{SE})$$

Thus the following equations are solved:

$$\begin{aligned} & \frac{1}{2} (\alpha) u_{i-1,j+1} + \frac{1}{2} (1 - \alpha) u_{i,j+1} \\ & + \frac{1}{2} (1 - \alpha) u_{i-1,j} + \frac{1}{2} (-4 + \alpha) u_{ij} + \frac{1}{2} (1 - \alpha) u_{i+1,j} \\ & + \frac{1}{2} (1 - \alpha) u_{i,j-1} + \frac{1}{2} (\alpha) u_{i+1,j-1} \\ & = -4h \end{aligned}$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

D03EEF discretizes a second order elliptic partial differential equation (PDE) on a rectangular region.

2. Specification

```

SUBROUTINE D03EEF (XMIN, XMAX, YMIN, YMAX, PDEF, BNDY,
1                NGX, NGY, LDA, A, RHS, SCHEME, IFAIL)
INTEGER          NGX, NGY, LDA, IFAIL
DOUBLE PRECISION XMIN, XMAX, YMIN, YMAX, A(LDA,7), RHS(LDA)
CHARACTER*1      SCHEME
EXTERNAL         PDEF, BNDY
    
```

3. Description

D03EEF discretizes a second order linear elliptic partial differential equation of the form

$$\begin{aligned}
 & (\alpha)(x,y) \frac{\partial^2 U}{\partial x^2} + (\beta)(x,y) \frac{\partial^2 U}{\partial x \partial y} + (\gamma)(x,y) \frac{\partial^2 U}{\partial y^2} \\
 & + (\delta)(x,y) \frac{\partial U}{\partial x} + (\epsilon)(x,y) \frac{\partial U}{\partial y} + (\phi)(x,y)U = (\psi)(x,y) \quad (1)
 \end{aligned}$$

on a rectangular region

$$\begin{aligned}
 & x \leq x \leq x \\
 & \quad A \quad B \\
 & y \leq y \leq y \\
 & \quad A \quad B
 \end{aligned}$$

subject to boundary conditions of the form

$$a(x,y)U + b(x,y) \frac{\partial U}{\partial n} = c(x,y)$$

$\frac{d^2U}{dn^2}$   
 where  $\frac{d}{dn}$  denotes the outward pointing normal derivative on the boundary. Equation (1) is said to be elliptic if

$$4(\alpha)(x,y)(\gamma)(x,y) \geq (\beta)(x,y)^2$$

for all points in the rectangular region. The linear equations produced are in a form suitable for passing directly to the multigrid routine D03EDF.

The equation is discretized on a rectangular grid, with  $n_x$  grid points in the x-direction and  $n_y$  grid points in the y-direction. The grid spacing used is therefore

$$h_x = (x_B - x_A) / (n_x - 1)$$

$$h_y = (y_B - y_A) / (n_y - 1)$$

and the co-ordinates of the grid points  $(x_{ij}, y_{ij})$  are

$$x_{ij} = x_A + (i-1)h_x, \quad i=1,2,\dots,n_x,$$

$$y_{ij} = y_A + (j-1)h_y, \quad j=1,2,\dots,n_y.$$

At each grid point  $(x_{ij}, y_{ij})$  six neighbouring grid points are used to approximate the partial differential equation, so that the equation is discretized on the following seven-point stencil:

Please see figure in printed Reference Manual

For convenience the approximation  $u_{ij}$  to the exact solution  $U(x_{ij}, y_{ij})$  is denoted by  $u_{ij}$ , and the neighbouring approximations are labelled according to points of the compass as shown. Where numerical labels for the seven points are required, these are also shown above.

The following approximations are used for the second derivatives:

$$\frac{\partial^2 U}{\partial x^2} \approx \frac{1}{h^2} (u_{i-2} - 2u_i + u_{i+2})$$

$$\frac{\partial^2 U}{\partial y^2} \approx \frac{1}{h^2} (u_{i-2} - 2u_i + u_{i+2})$$

$$\frac{\partial^2 U}{\partial x \partial y} \approx \frac{1}{4h^2} (u_{i-2, j-1} - u_{i-2, j+1} + u_{i+2, j-1} - u_{i+2, j+1})$$

Two possible schemes may be used to approximate the first derivatives:

Central Differences

$$\frac{\partial U}{\partial x} \approx \frac{1}{2h} (u_{i-1} - u_{i+1})$$

$$\frac{\partial U}{\partial y} \approx \frac{1}{2h} (u_{i-1} - u_{i+1})$$

Upwind Differences

$$\frac{\partial U}{\partial x} \approx \frac{1}{h} (u_i - u_{i+1}) \text{ if } (\text{delta})(x,y) > 0$$

$$\frac{\partial U}{\partial x} \approx \frac{1}{h} (u_{i-1} - u_i) \text{ if } (\text{delta})(x,y) < 0$$

$$\begin{aligned} \frac{ddU}{ddy} &= \frac{1}{h} \left( \frac{u_{N+1} - u_N}{\Delta y} \right) \text{if } (\text{epsilon})(x,y) > 0 \\ \frac{ddU}{ddy} &= \frac{1}{h} \left( \frac{u_N - u_{N-1}}{\Delta y} \right) \text{if } (\text{epsilon})(x,y) < 0. \end{aligned}$$

Central differences are more accurate than upwind differences, but upwind differences may lead to a more diagonally dominant matrix for those problems where the coefficients of the first derivatives are significantly larger than the coefficients of the second derivatives.

The approximations used for the first derivatives may be written in a more compact form as follows:

$$\begin{aligned} \frac{ddU}{ddx} &= \frac{1}{2h} \left( (k_x - 1)u_{x-1} - 2k_x u_x + (k_x + 1)u_{x+1} \right) \\ \frac{ddU}{ddy} &= \frac{1}{2h} \left( (k_y - 1)u_{y-1} - 2k_y u_y + (k_y + 1)u_{y+1} \right) \end{aligned}$$

where  $k_x = \text{sign}(\Delta x)$  and  $k_y = \text{sign}(\Delta y)$  for upwind differences, and  $k_x = k_y = 0$  for central differences.

At all points in the rectangular domain, including the boundary, the coefficients in the partial differential equation are evaluated by calling the user-supplied subroutine PDEF, and applying the approximations. This leads to a seven-diagonal system of linear equations of the form:

$$\begin{aligned} &A_{ij} u_{i-1,j+1} + A_{ij} u_{i,j+1} \\ &+ A_{ij} u_{i-1,j} + A_{ij} u_{ij} + A_{ij} u_{i+1,j} \\ &+ A_{ij} u_{i,j-1} + A_{ij} u_{i+1,j-1} = f_{ij}, \quad i=1,2,\dots,n; j=1,2,\dots,n, \end{aligned}$$

where the coefficients are given by

$$A_{ij} = (\beta)_{ij} \frac{1}{x^2 y^2} + (\gamma)_{ij} \frac{1}{x^2 y} + (\epsilon)_{ij} \frac{1}{x y^2} - (k-1)$$

$$A_{ij} = -(\beta)_{ij} \frac{1}{x^2 y}$$

$$A_{ij} = (\alpha)_{ij} \frac{1}{x^2} + (\beta)_{ij} \frac{1}{x^2 y} + (\delta)_{ij} \frac{1}{x^2 y} - (k-1)$$

$$A_{ij} = -(\alpha)_{ij} \frac{2}{x^2} - (\beta)_{ij} \frac{1}{x^2 y} - (\gamma)_{ij} \frac{2}{x^2 y}$$

$$-(\delta)_{ij} \frac{k}{x^2 y} - (\epsilon)_{ij} \frac{k}{x^2 y} - (\phi)_{ij}$$

$$A_{ij} = (\alpha)_{ij} \frac{1}{x^2} + (\beta)_{ij} \frac{1}{x^2 y} + (\delta)_{ij} \frac{1}{x^2 y} - (k+1)$$

$$A_{ij} = -(\beta)_{ij} \frac{1}{x^2 y}$$

$$A_{ij} = (\beta)_{ij} \frac{1}{x^2 y} + (\gamma)_{ij} \frac{1}{x^2 y} + (\epsilon)_{ij} \frac{1}{x^2 y} - (k+1)$$

$$f_{ij} = (\psi)_{ij}$$

These equations then have to be modified to take account of the boundary conditions. These may be Dirichlet (where the solution is given), Neumann (where the derivative of the solution is given), or mixed (where a linear combination of solution and derivative is given).

If the boundary conditions are Dirichlet, there are an infinity of possible equations which may be applied:

$$(\mu)u_{ij} = (\mu)f_{ij}, \quad (\mu) \neq 0. \quad (2)$$

If DO3EDF is used to solve the discretized equations, it turns out that the choice of  $(\mu)$  can have a dramatic effect on the rate of convergence, and the obvious choice  $(\mu)=1$  is not the best. Some choices may even cause the multigrid method to fail altogether. In practice it has been found that a value of the same order as the other diagonal elements of the matrix is best, and the following value has been found to work well in practice:

$$(\mu) = \min_{ij} \left( \frac{2}{h} \frac{2}{h} \right) \frac{4}{x^2 + y^2}.$$

If the boundary conditions are either mixed or Neumann (i.e.,  $B \neq 0$  on return from the user-supplied subroutine BNDY), then one of the points in the seven-point stencil lies outside the domain. In this case the normal derivative in the boundary conditions is used to eliminate the 'fictitious' point,  $u_{\text{outside}}$ :

$$\frac{ddU}{ddn} = \frac{1}{2h} (u_{\text{outside}} - u_{\text{inside}}). \quad (3)$$

It should be noted that if the boundary conditions are Neumann and  $(\phi)(x,y)=0$ , then there is no unique solution. The routine returns with IFAIL = 5 in this case, and the seven-diagonal matrix is singular.

The four corners are treated separately. The user-supplied subroutine BNDY is called twice, once along each of the edges meeting at the corner. If both boundary conditions at this point are Dirichlet and the prescribed solution values agree, then this value is used in an equation of the form (2). If the prescribed solution is discontinuous at the corner, then the average of the two values is used. If one boundary condition is Dirichlet and the other is mixed, then the value prescribed by the Dirichlet

condition is used in an equation of the form given above. Finally, if both conditions are mixed or Neumann, then two 'fictitious' points are eliminated using two equations of the form (3).

It is possible that equations for which the solution is known at all points on the boundary, have coefficients which are not defined on the boundary. Since this routine calls the user-supplied subroutine PDEF at all points in the domain, including boundary points, arithmetic errors may occur in the user's routine PDEF which this routine cannot trap. If the user has an equation with Dirichlet boundary conditions (i.e.,  $B = 0$  at all points on the boundary), but with PDE coefficients which are singular on the boundary, then D03EDF could be called directly only using interior grid points with the user's own discretization.

After the equations have been set up as described above, they are checked for diagonal dominance. That is to say,

$$|A_{ij}| > \sum_{k \neq j} |A_{ik}|, \quad i=1,2,\dots,n; \quad j=1,2,\dots,n.$$

If this condition is not satisfied then the routine returns with IFAIL = 6. The multigrid routine D03EDF may still converge in this case, but if the coefficients of the first derivatives in the partial differential equation are large compared with the coefficients of the second derivative, the user should consider using upwind differences (SCHEME = 'U').

Since this routine is designed primarily for use with D03EDF, this document should be read in conjunction with the document for that routine.

#### 5. Parameters

- 1: XMIN -- DOUBLE PRECISION Input  
 2: XMAX -- DOUBLE PRECISION Input  
 On entry: the lower and upper x co-ordinates of the rectangular region respectively,  $x_A$  and  $x_B$ . Constraint: XMIN  $\leq$  XMAX

< XMAX.

3: YMIN -- DOUBLE PRECISION Input

4: YMAX -- DOUBLE PRECISION Input

On entry: the lower and upper y co-ordinates of the rectangular region respectively,  $y_A$  and  $y_B$ . Constraint: YMIN < YMAX.

5: PDEF -- SUBROUTINE, supplied by the user.

External Procedure

PDEF must evaluate the functions  $(\alpha)(x,y)$ ,  $(\beta)(x,y)$ ,  $(\gamma)(x,y)$ ,  $(\delta)(x,y)$ ,  $(\epsilon)(x,y)$ ,  $(\phi)(x,y)$  and  $(\psi)(x,y)$  which define the equation at a general point  $(x,y)$ .

Its specification is:

```

SUBROUTINE PDEF (X, Y, ALPHA, BETA, GAMMA,
1              DELTA, EPSLON, PHI, PSI)
DOUBLE PRECISION X, Y, ALPHA, BETA, GAMMA, DELTA,
1              EPSLON, PHI, PSI

```

1: X -- DOUBLE PRECISION Input

2: Y -- DOUBLE PRECISION Input

On entry: the x and y co-ordinates of the point at which the coefficients of the partial differential equation are to be evaluated. 8

3: ALPHA -- DOUBLE PRECISION Output

4: BETA -- DOUBLE PRECISION Output

5: GAMMA -- DOUBLE PRECISION Output

6: DELTA -- DOUBLE PRECISION Output

7: EPSLON -- DOUBLE PRECISION Output

8: PHI -- DOUBLE PRECISION Output

9: PSI -- DOUBLE PRECISION Output

On exit: ALPHA, BETA, GAMMA, DELTA, EPSLON, PHI and PSI must be set to the values of  $(\alpha)(x,y)$ ,  $(\beta)(x,y)$ ,  $(\gamma)(x,y)$ ,  $(\delta)(x,y)$ ,  $(\epsilon)(x,y)$ ,  $(\phi)(x,y)$  and  $(\psi)(x,y)$  respectively at the point specified by X and Y.

PDEF must be declared as EXTERNAL in the (sub)program

from which D03EEF is called. Parameters denoted as  
Input must not be changed by this procedure.

- 6: BNDY -- SUBROUTINE, supplied by the user. External Procedure  
BNDY must evaluate the functions  $a(x,y)$ ,  $b(x,y)$ , and  $c(x,y)$   
involved in the boundary conditions.

Its specification is:

```

SUBROUTINE BNDY (X, Y, A, B, C, IBND)
INTEGER          IBND
DOUBLE PRECISION X, Y, A, B, C

```

- 1: X -- DOUBLE PRECISION Input
- 2: Y -- DOUBLE PRECISION Input  
On entry: the x and y co-ordinates of the point at  
which the boundary conditions are to be evaluated.
- 3: A -- DOUBLE PRECISION Output
- 4: B -- DOUBLE PRECISION Output
- 5: C -- DOUBLE PRECISION Output  
On exit: A, B and C must be set to the values of the  
functions appearing in the boundary conditions.
- 6: IBND -- INTEGER Input  
On entry: specifies on which boundary the point (X,Y)  
lies. IBND = 0, 1, 2 or 3 according as the point lies  
on the bottom, right, top or left boundary.  
BNDY must be declared as EXTERNAL in the (sub)program  
from which D03EEF is called. Parameters denoted as  
Input must not be changed by this procedure.
- 7: NGX -- INTEGER Input
- 8: NGY -- INTEGER Input  
On entry: the number of interior grid points in the x- and y  
-directions respectively,  $n_x$  and  $n_y$ . If the seven-diagonal  
equations are to be solved by D03EDF, then  $NGX-1$  and  $NGY-1$   
should preferably be divisible by as high a power of 2 as  
possible. Constraint:  $NGX \geq 3$ ,  $NGY \geq 3$ .
- 9: LDA -- INTEGER Input  
On entry:  
the first dimension of the array A as declared in the  
(sub)program from which D03EEF is called.

Constraint: if only the seven-diagonal equations are required, then  $LDA \geq NGX*NGY$ . If a call to this routine is to be followed by a call to D03EDF to solve the seven-diagonal linear equations,  $LDA \geq (4*(NGX+1)*(NGY+1))/3$ .

Note: this routine only checks the former condition. D03EDF, if called, will check the latter condition.

10: A(LDA,7) -- DOUBLE PRECISION array Output  
 On exit: A(i,j), for  $i=1,2,\dots,NGX*NGY$ ;  $j = 1,2,\dots,7$ , contains the seven-diagonal linear equations produced by the discretization described above. If  $LDA > NGX*NGY$ , the remaining elements are not referenced by the routine, but if  $LDA \geq (4*(NGX+1)*(NGY+1))/3$  then the array A can be passed directly to D03EDF, where these elements are used as workspace.

11: RHS(LDA) -- DOUBLE PRECISION array Output  
 On exit: the first  $NGX*NGY$  elements contain the right-hand sides of the seven-diagonal linear equations produced by the discretization described above. If  $LDA > NGX*NGY$ , the remaining elements are not referenced by the routine, but if  $LDA \geq (4*(NGY+1)*(NGY+1))/3$  then the array RHS can be passed directly to D03EDF, where these elements are used as workspace.

12: SCHEME -- CHARACTER\*1 Input  
 On entry: the type of approximation to be used for the first derivatives which occur in the partial differential equation.

If SCHEME = 'C', then central differences are used.

If SCHEME = 'U', then upwind differences are used.

Constraint: SCHEME = 'C' or 'U'.

Note: generally speaking, if at least one of the coefficients multiplying the first derivatives (DELTA or EPSLON as returned by PDEF) are large compared with the coefficients multiplying the second derivatives, then upwind differences may be more appropriate. Upwind differences are less accurate than central differences, but may result in more rapid convergence for strongly convective equations. The easiest test is to try both schemes.

13: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL  $\neq$  0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit.

## 6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

### IFAIL= 1

On entry  $XMIN \geq XMAX$ ,

or  $YMIN \geq YMAX$ ,

or  $NGX < 3$ ,

or  $NGY < 3$ ,

or  $LDA < NGX*NGY$ ,

or SCHEME is not one of 'C' or 'U'.

### IFAIL= 2

At some point on the boundary there is a derivative in the boundary conditions ( $B \neq 0$  on return from a BNDY) and there

is a non-zero coefficient of the mixed derivative  $\frac{\partial^2 U}{\partial x \partial y}$

( $BETA \neq 0$  on return from PDEF).

### IFAIL= 3

A null boundary has been specified, i.e., at some point both A and B are zero on return from a call to BNDY.

### IFAIL= 4

The equation is not elliptic, i.e.,  $4*ALPHA*GAMMA < BETA$  after a call to PDEF. The discretization has been completed, but the convergence of D03EDF cannot be guaranteed.

### IFAIL= 5

The boundary conditions are purely Neumann (only the derivative is specified) and there is, in general, no unique

D03 -- Partial Differential Equations D03FAF  
 D03FAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

D03FAF solves the Helmholtz equation in Cartesian co-ordinates in three dimensions using the standard seven-point finite difference approximation. This routine is designed to be particularly efficient on vector processors.

### 2. Specification

```

4                (LWRK)

```

### 3. Description

D03FAF solves the three-dimensional Helmholtz equation in cartesian co-ordinates:

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} + (\text{lambda})u = f(x,y,z)$$

This subroutine forms the system of linear equations resulting from the standard seven-point finite difference equations, and then solves the system using a method based on the fast Fourier transform (FFT) described by Swarztrauber [1]. This subroutine is based on the routine HW3CRT from FISHPACK (see Swarztrauber and Sweet [2]).

More precisely, the routine replaces all the second derivatives by second-order central difference approximations, resulting in a

block tridiagonal system of linear equations. The equations are modified to allow for the prescribed boundary conditions. Either the solution or the derivative of the solution may be specified on any of the boundaries, or the solution may be specified to be periodic in any of the three dimensions. By taking the discrete Fourier transform in the x- and y-directions, the equations are reduced to sets of tridiagonal systems of equations. The Fourier transforms required are computed using the multiple FFT routines found in Chapter C06 of the NAG Fortran Library.

#### 5. Parameters

- 1: XS -- DOUBLE PRECISION Input  
 On entry: the lower bound of the range of x, i.e.,  $XS \leq x \leq XF$ . Constraint:  $XS < XF$ .
- 2: XF -- DOUBLE PRECISION Input  
 On entry: the upper bound of the range of x, i.e.,  $XS \leq x \leq XF$ . Constraint:  $XS < XF$ .
- 3: L -- INTEGER Input  
 On entry: the number of panels into which the interval (XS,XF) is subdivided. Hence, there will be L+1 grid points in the x-direction given by  $x = XS + (i-1) \cdot (\Delta x)$ , for  $i = 1, 2, \dots, L+1$ , where  $(\Delta x) = (XF - XS) / L$  is the panel width. Constraint:  $L \geq 5$ .
- 4: LBDCND -- INTEGER Input  
 On entry: indicates the type of boundary conditions at  $x = XS$  and  $x = XF$ .  
 LBDCND = 0  
     if the solution is periodic in x, i.e.,  
      $u(XS, y, z) = u(XF, y, z)$ .  
 LBDCND = 1  
     if the solution is specified at  $x = XS$  and  $x = XF$ .  
 LBDCND = 2  
     if the solution is specified at  $x = XS$  and the

derivative of the solution with respect to  $x$  is specified at  $x = XF$ .

LBDCND = 3

if the derivative of the solution with respect to  $x$  is specified at  $x = XS$  and  $x = XF$ .

LBDCND = 4

if the derivative of the solution with respect to  $x$  is specified at  $x = XS$  and the solution is specified at  $x = XF$ .

Constraint:  $0 \leq \text{LBDCND} \leq 4$ .

- 5: BDXS(MDIMF,N+1) -- DOUBLE PRECISION array Input  
 On entry: the values of the derivative of the solution with respect to  $x$  at  $x = XS$ . When LBDCND = 3 or 4, BDXS(j,k)=u(x, y, z), for  $j=1,2,\dots,M+1$ ;  $k=1,2,\dots,N+1$ .

When LBDCND has any other value, BDXS is not referenced.

- 6: BDXF(MDIMF,N+1) -- DOUBLE PRECISION array Input  
 On entry: the values of the derivative of the solution with respect to  $x$  at  $x = XF$ . When LBDCND = 2 or 3, BDXF(j,k) = u(x, y, z), for  $j=1,2,\dots,M+1$ ;  $k=1,2,\dots,N+1$ .

When LBDCND has any other value, BDXF is not referenced.

- 7: YS -- DOUBLE PRECISION Input  
 On entry: the lower bound of the range of  $y$ , i.e.,  $YS \leq y \leq YF$ . Constraint:  $YS < YF$ .

- 8: YF -- DOUBLE PRECISION Input  
 On entry: the upper bound of the range of  $y$ , i.e.,  $YS \leq y \leq YF$ . Constraint:  $YS < YF$ .

- 9: M -- INTEGER Input  
 On entry: the number of panels into which the interval (YS,YF) is subdivided. Hence, there will be  $M+1$  grid points in the  $y$ -direction given by  $y_j = YS + (j-1)*(\text{delta})y$  for  $j=1,2,\dots,M+1$ , where  $(\text{delta})y=(YF-YS)/M$  is the panel width. Constraint:  $M \geq 5$ .

- 10: MBDCND -- INTEGER Input  
 On entry: indicates the type of boundary conditions at  $y = YS$  and  $y = YF$ .  
 MBDCND = 0  
 if the solution is periodic in  $y$ , i.e.,

$$u(x, YF, z) = u(x, YS, z).$$

MBDCND = 1

if the solution is specified at  $y = YS$  and  $y = YF$ .

MBDCND = 2

if the solution is specified at  $y = YS$  and the derivative of the solution with respect to  $y$  is specified at  $y = YF$ .

MBDCND = 3

if the derivative of the solution with respect to  $y$  is specified at  $y = YS$  and  $y = YF$ .

MBDCND = 4

if the derivative of the solution with respect to  $y$  is specified at  $y = YS$  and the solution is specified at  $y = YF$ .

Constraint:  $0 \leq \text{MBDCND} \leq 4$ .

- 11: BDYS(LDIMF,N+1) -- DOUBLE PRECISION array Input  
 On entry: the values of the derivative of the solution with respect to  $y$  at  $y = YS$ . When MBDCND = 3 or 4, BDYS  
 $(i,k) = u(x, y, z)$ , for  $i=1,2,\dots,L+1$ ;  $k=1,2,\dots,N+1$ .  
 $y \quad i \quad s \quad k$

When MBDCND has any other value, BDYS is not referenced.

- 12: BDYF(LDIMF,N+1) -- DOUBLE PRECISION array Input  
 On entry: the values of the derivative of the solution with respect to  $y$  at  $y = YF$ . When MBDCND = 2 or 3, BDYF  
 $(i,k) = u(x, YF, z)$ , for  $i=1,2,\dots,L+1$ ;  $k=1,2,\dots,N+1$ .  
 $y \quad i \quad k$

When MBDCND has any other value, BDYF is not referenced.

- 13: ZS -- DOUBLE PRECISION Input  
 On entry: the lower bound of the range of  $z$ , i.e.,  $ZS \leq z \leq ZF$ . Constraint:  $ZS < ZF$ .

- 14: ZF -- DOUBLE PRECISION Input  
 On entry: the upper bound of the range of  $z$ , i.e.,  $ZS \leq z \leq ZF$ . Constraint:  $ZS < ZF$ .

- 15: N -- INTEGER Input  
 On entry: the number of panels into which the interval  $(ZS, ZF)$  is subdivided. Hence, there will be  $N+1$  grid points in the  $z$ -direction given by  $z = ZS + (k-1) \cdot (\text{delta}z)$ , for  
 $k$   
 $k=1,2,\dots,N+1$ , where  $(\text{delta}z) = (ZF - ZS) / N$  is the panel width.

Constraint:  $N \geq 5$ .

- 16: NDBCND -- INTEGER Input  
 On entry: specifies the type of boundary conditions at  $z = ZS$  and  $z = ZF$ .  
 NDBCND = 0  
     if the solution is periodic in  $z$ , i.e.,  
      $u(x,y,ZF)=u(x,y,ZS)$ .
- NDBCND = 1  
     if the solution is specified at  $z = ZS$  and  $z = ZF$ .
- NDBCND = 2  
     if the solution is specified at  $z = ZS$  and the  
     derivative of the solution with respect to  $z$  is  
     specified at  $z = ZF$ .
- NDBCND = 3  
     if the derivative of the solution with respect to  $z$  is  
     specified at  $z = ZS$  and  $z = ZF$ .
- NDBCND = 4  
     if the derivative of the solution with respect to  $z$  is  
     specified at  $z = ZS$  and the solution is specified at  $z$   
     =  $ZF$ .
- Constraint:  $0 \leq NDBCND \leq 4$ .
- 17: BDZS(LDIMF,M+1) -- DOUBLE PRECISION array Input  
 On entry: the values of the derivative of the solution with  
 respect to  $z$  at  $z = ZS$ . When NDBCND = 3 or 4, BDZS  
 $(i,j)=u(x,y,ZS)=u(x,y,z)$ , for  $i=1,2,\dots,L+1$ ;  
      $z$   $i$   $j$   
 $j=1,2,\dots,M+1$ .
- When NDBCND has any other value, BDZS is not referenced.
- 18: BDZF(LDIMF,M+1) -- DOUBLE PRECISION array Input  
 On entry: the values of the derivative of the solution with  
 respect to  $z$  at  $z = ZF$ . When NDBCND = 2 or 3, BDZF  
 $(i,j)=u(x,y,ZF)=u(x,y,z)$ , for  $i=1,2,\dots,L+1$ ;  
      $z$   $i$   $j$   
 $j=1,2,\dots,M+1$ .
- When NDBCND has any other value, BDZF is not referenced.
- 19: LAMBDA -- DOUBLE PRECISION Input  
 On entry: the constant ( $\lambda$ ) in the Helmholtz equation.  
 For certain positive values of ( $\lambda$ ) a solution to the  
 differential equation may not exist, and close to these  
 values the solution of the discretized problem will be

extremely ill-conditioned. If  $(\lambda) > 0$ , then D03FAF will set IFAIL to 3, but will still attempt to find a solution. However, since in general the values of  $(\lambda)$  for which no solution exists cannot be predicted a priori, the user is advised to treat any results computed with  $(\lambda) > 0$  with great caution.

20: LDIMF -- INTEGER Input

On entry:

the first dimension of the arrays F, BDYS, BDYF, BDZS and BDZF as declared in the (sub)program from which D03FAF is called.

Constraint: LDIMF  $\geq L + 1$ .

21: MDIMF -- INTEGER Input

On entry: the second dimension of the array F and the first dimension of the arrays BDXS and BDXF as declared in the (sub)program from which D03FAF is called.

Constraint: MDIMF  $\geq M + 1$ .

22: F(LDIMF,MDIMF,N+1) -- DOUBLE PRECISION array Input/Output

On entry: the values of the right-side of the Helmholtz equation and boundary values (if any).

$$F(i,j,k) = f(x_i, y_j, z_k) \quad i=2,3,\dots,L, \quad j=2,3,\dots,M \text{ and } k=2,3,\dots,N.$$

On the boundaries F is defined by

LBDCND  $F(1,j,k) \quad F(L+1,j,k)$

0  $f(x_j, y_k, z) \quad f(x_j, y_k, z)$

1  $u(x_j, y_k, z) \quad u(x_j, y_k, z)$

2  $u(x_j, y_k, z) \quad f(x_j, y_k, z) \quad j=1,2,\dots,M+1$

3  $f(x_j, y_k, z) \quad f(x_j, y_k, z) \quad k=1,2,\dots,N+1$

4  $f(x_j, y_k, z) \quad u(x_j, y_k, z)$

MBDCND  $F(i,1,k) \quad F(i,M+1,k)$

```

0      f(x ,YS,z )f(x ,YS,z )
        i      k i      k

1      u(x ,YS,z )u(x ,YF,z )
        i      k i      k

2      u(x ,YS,z )f(x ,YF,z ) i=1,2,...,L+1
        i      k i      k

3      f(x ,YS,z )f(x ,YF,z ) k=1,2,...,N+1
        i      k i      k

4      f(x ,YS,z )u(x ,YF,z )
        i      k i      k

```

```

NBDCND  F(i,j,1) F(i,j,N+1
          )

```

```

0      f(x ,y ,ZS)f(x ,y ,ZS)
        i j      i j

1      u(x ,y ,ZS)u(x ,y ,ZF)
        i j      i j

2      u(x ,y ,ZS)f(x ,y ,ZF) i=1,2,...,L+1
        i j      i j

3      f(x ,y ,ZS)f(x ,y ,ZF) j=1,2,...,M+1
        i j      i j

4      f(x ,y ,ZS)u(x ,y ,ZF)
        i j      i j

```

Note: if the table calls for both the solution u and the right-hand side f on a boundary, then the solution must be specified. On exit: F contains the solution u(i,j,k) of the finite difference approximation for the grid point ( x ,y ,z ) for i=1,2,...,L+1, j=1,2,...,M+1 and k=1,2,...,N+1.

```

i j k

```

23: PERTRB -- DOUBLE PRECISION Output  
 On exit: PERTRB = 0, unless a solution to Poisson's equation ((lambda)=0) is required with a combination of periodic or derivative boundary conditions (LBDCND, MBDCND and NBDCND = 0 or 3). In this case a solution may not exist. PERTRB is a constant, calculated and subtracted from the array F, which ensures that a solution exists. D03FAF then computes this solution, which is a least-squares solution to

the original approximation. This solution is not unique and is unnormalised. The value of PERTRB should be small compared to the right-hand side F, otherwise a solution has been obtained to an essentially different problem. This comparison should always be made to insure that a meaningful solution has been obtained.

24: W(LWRK) -- DOUBLE PRECISION array Workspace

25: LWRK -- INTEGER Input

On entry:

the dimension of the array W as declared in the (sub)program from which D03FAF is called.

$LRWK \geq 2 \cdot (N+1) \cdot \max(L, M) + 3 \cdot L + 3 \cdot M + 4 \cdot N + 6$  is an upper bound on the required size of W. If LWRK is too small, the routine exits with IFAIL = 2, and if on entry IFAIL = 0 or IFAIL = -1, a message is output giving the exact value of LWRK required to solve the current problem.

26: IFAIL -- INTEGER Input/Output

On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL  $\neq$  0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit.

## 6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry  $XS \geq XF$ ,

or  $L < 5$ ,

or  $LBDCND < 0$ ,

or  $LBDCND > 4$ ,

or  $YS \geq YF$ ,

- or  $M < 5,$
- or  $MBDCND < 0,$
- or  $MBDCND > 4,$
- or  $ZS \geq ZF,$
- or  $N < 5,$
- or  $NBDCND < 0,$
- or  $NBDCND > 4,$
- or  $LDIMF < L + 1 > 0,$
- or  $MDIMF < M + 1.$

IFAIL= 2  
 On entry LWRK is too small.

IFAIL= 3  
 On entry (lambda) > 0.

7. Accuracy

None.

8. Further Comments

The execution time is roughly proportional to  $L \cdot M \cdot N \cdot (\log L + \log M + 5)$ , but also depends on input parameters  $LBDCND$  and  $MBDCND$ .

9. Example

The example solves the Helmholtz equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} + (\lambda)u = f(x,y,z)$$

for  $(x,y,z)$  is in  $[0,1] \times [0,2(\pi)] \times [0, \frac{\pi}{2}]$  where  $(\lambda) = -2$ , and  $f(x,y,z)$  is derived from the exact solution

$$u(x,y,z) = x \sin(y) \cos(z).$$

The equation is subject to the following boundary conditions, again derived from the exact solution given above.

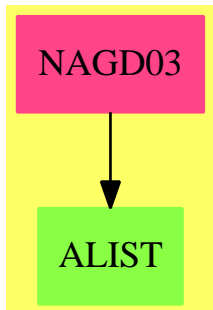

$u(0,y,z)$  and  $u(1,y,z)$  are prescribed (i.e., LBDCND = 1).

$u(x,0,z) = u(x,2(\pi),z)$  (i.e., MBDCND = 0).

$u(x,y,0)$  and  $u(x,y, \frac{\pi}{2})$  are prescribed (i.e. NBDCND = 2).

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

— NagPolynomialRootsPackage.help —

This package uses the NAG Library to compute the zeros of a polynomial

write:

$$f(z) = a_0 (z - z_1)^{m_1} (z - z_2)^{m_2} \dots (z - z_k)^{m_k}, \quad k \leq n,$$

with distinct zeros  $z_1, z_2, \dots, z_k$  and multiplicities  $m_i \geq 1$ . If  $m_i = 1$ ,  $z_i$  is called a single zero, if  $m_i > 1$ ,  $z_i$  is called a multiple or repeated zero; a multiple zero is also a zero of the derivative of  $f(z)$ .

If the coefficients of  $f(z)$  are all real, then the zeros of  $f(z)$  are either real or else occur as pairs of conjugate complex numbers  $x+iy$  and  $x-iy$ . A pair of complex conjugate zeros are the zeros of a quadratic factor of  $f(z)$ ,  $(z + rz + s)$ , with real coefficients  $r$  and  $s$ .

Mathematicians are accustomed to thinking of polynomials as pleasantly simple functions to work with. However the problem of numerically computing the zeros of an arbitrary polynomial is far from simple. A great variety of algorithms have been proposed, of which a number have been widely used in practice; for a fairly comprehensive survey, see Householder [1]. All general algorithms are iterative. Most converge to one zero at a time; the corresponding factor can then be divided out as in equation (1) above - this process is called deflation or, loosely, dividing out the zero - and the algorithm can be applied again to the polynomial  $f(z)$ . A pair of complex conjugate zeros can be divided out together - this corresponds to dividing  $f(z)$  by a quadratic factor.

Whatever the theoretical basis of the algorithm, a number of practical problems arise: for a thorough discussion of some of them see Peters and Wilkinson [2] and Wilkinson [3]. The most elementary point is that, even if  $z_1$  is mathematically an exact zero of  $f(z)$ , because of the fundamental limitations of computer arithmetic the computed value of  $f(z_1)$  will not necessarily be exactly 0.0. In practice there is usually a small region of values of  $z$  about the exact zero at which the computed value of  $f(z)$  becomes swamped by rounding errors. Moreover in many algorithms this inaccuracy in the computed value of  $f(z)$  results in a similar inaccuracy in the computed step from one iterate to the next. This limits the precision with which any zero can be

computed. Deflation is another potential cause of trouble, since, in the notation of equation (1), the computed coefficients of  $f(z)$  will not be completely accurate, especially if  $z$  is not an exact zero of  $f(z)$ ; so the zeros of the computed  $f(z)$  will deviate from the zeros of  $f(z)$ .

A zero is called ill-conditioned if it is sensitive to small changes in the coefficients of the polynomial. An ill-conditioned zero is likewise sensitive to the computational inaccuracies just mentioned. Conversely a zero is called well-conditioned if it is comparatively insensitive to such perturbations. Roughly speaking a zero which is well separated from other zeros is well-conditioned, while zeros which are close together are ill-conditioned, but in talking about 'closeness' the decisive factor is not the absolute distance between neighbouring zeros but their ratio: if the ratio is close to 1 the zeros are ill-conditioned. In particular, multiple zeros are ill-conditioned. A multiple zero is usually split into a cluster of zeros by perturbations in the polynomial or computational inaccuracies.

## 3. Recommendations on Choice and Use of Routines

### 3.1. Discussion

Two routines are available: CO2AFF for polynomials with complex coefficients and CO2AGF for polynomials with real coefficients.

CO2AFF and CO2AGF both use a variant of Laguerre's Method due to BT Smith to calculate each zero until the degree of the deflated polynomial is less than 3, whereupon the remaining zeros are obtained using the 'standard' closed formulae for a quadratic or linear equation.

The accuracy of the roots will depend on how ill-conditioned they are. Peters and Wilkinson [2] describe techniques for estimating the errors in the zeros after they have been computed.

C02AFF(3NAG) Foundation Library (12/10/92) C02AFF(3NAG)

C02 -- Zeros of Polynomials C02AFF  
 C02AFF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

C02AFF finds all the roots of a complex polynomial equation, using a variant of Laguerre's Method.

## 2. Specification

```

SUBROUTINE C02AFF (A, N, SCALE, Z, W, IFAIL)
  INTEGER          N, IFAIL
  DOUBLE PRECISION A(2,N+1), Z(2,N), W(4*(N+1))
  LOGICAL          SCALE
  
```

## 3. Description

The routine attempts to find all the roots of the nth degree complex polynomial equation

$$P(z) = a_0 z^n + a_1 z^{n-1} + a_2 z^{n-2} + \dots + a_{n-1} z + a_n = 0.$$

The roots are located using a modified form of Laguerre's Method,

originally proposed by Smith [2].

The method of Laguerre [3] can be described by the iterative scheme

$$L(z)_k = z_{k+1} - z_k = \frac{-n * P(z)_k}{P'(z)_k + \frac{-n * P(z)_k}{H(z)_k}}$$

where  $H(z)_k = (n-1) * [(n-1) * (P'(z)_k)^2 - n * P(z)_k * P''(z)_k]$ , and  $z_0$  is specified.

The sign in the denominator is chosen so that the modulus of the Laguerre step at  $z_k$ , viz.  $|L(z)_k|$ , is as small as possible. The method can be shown to be cubically convergent for isolated roots (real or complex) and linearly convergent for multiple roots. The routine generates a sequence of iterates  $z_1, z_2, z_3, \dots$ , such that  $|P(z)_{k+1}| < |P(z)_k|$  and ensures that  $z_{k+1} + L(z)_k$  'roughly' lies inside a circular region of radius  $|F|$  about  $z_k$  known to contain a zero of  $P(z)$ ; that is,  $|L(z)_{k+1}| \leq |F|$ , where  $F$  denotes the Fejer bound (see Marden [1]) at the point  $z_k$ . Following Smith [2],  $F$  is taken to be  $\min(B, 1.445 * n * R)$ , where  $B$  is an upper bound for the magnitude of the smallest zero given by

$$B = 1.0001 * \min(\frac{1}{n} * |L(z)_k|, |r_1|, |a_n / a_0|)$$

$r_1$  is the zero  $X$  of smaller magnitude of the quadratic equation

$$2 * (P''(z)_k / (2 * n * (n-1))) * X^2 + 2 * (P'(z)_k / n) * X + P(z)_k = 0$$

and the Cauchy lower bound  $R$  for the smallest zero is computed (using Newton's Method) as the positive root of the polynomial equation

$$|a_0 z^n + a_1 z^{n-1} + a_2 z^{n-2} + \dots + a_{n-1} z + a_n| = 0.$$

Starting from the origin, successive iterates are generated according to the rule  $z_{k+1} = z_k + L(z_k)$  for  $k = 1, 2, 3, \dots$  and  $L(z_k)$  is 'adjusted' so that  $|P(z_{k+1})| < |P(z_k)|$  and  $|L(z_{k+1})| \leq |F|$ . The iterative procedure terminates if  $P(z_{k+1})$  is smaller in absolute value than the bound on the rounding error in  $P(z_{k+1})$  and the current iterate  $z_{k+1}$  is taken to be a zero of  $P(z)$ . The

deflated polynomial  $P(z) = P(z)/(z - z_{k+1})$  of degree  $n-1$  is then

formed, and the above procedure is repeated on the deflated polynomial until  $n < 3$ , whereupon the remaining roots are obtained via the 'standard' closed formulae for a linear ( $n = 1$ ) or quadratic ( $n = 2$ ) equation.

To obtain the roots of a quadratic polynomial, C02AHF(\*) can be used.

#### 5. Parameters

- 1: A(2,N+1) -- DOUBLE PRECISION array Input  
 On entry: if A is declared with bounds (2,0:N), then A(1,i) and A(2,i) must contain the real and imaginary parts of  $a_i$   
 (i.e., the coefficient of  $z^{n-i}$ ), for  $i=0,1,\dots,n$ .  
 Constraint: A(1,0) /= 0.0 or A(2,0) /= 0.0.
- 2: N -- INTEGER Input

On entry: the degree of the polynomial,  $n$ . Constraint:  $N \geq 1$ .

- 3: SCALE -- LOGICAL Input  
 On entry: indicates whether or not the polynomial is to be scaled. See Section 8 for advice on when it may be preferable to set SCALE = .FALSE. and for a description of the scaling strategy. Suggested value: SCALE = .TRUE..
- 4: Z(2,N) -- DOUBLE PRECISION array Output  
 On exit: the real and imaginary parts of the roots are stored in Z(1,i) and Z(2,i) respectively, for  $i=1,2,\dots,n$ .
- 5: W(4\*(N+1)) -- DOUBLE PRECISION array Workspace
- 6: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry  $A(1,0) = 0.0$  and  $A(2,0) = 0.0$ ,

or  $N < 1$ .

IFAIL= 2

The iterative procedure has failed to converge. This error is very unlikely to occur. If it does, please contact NAG immediately, as some basic assumption for the arithmetic has been violated. See also Section 8.

IFAIL= 3

Either overflow or underflow prevents the evaluation of  $P(z)$  near some of its zeros. This error is very unlikely to occur. If it does, please contact NAG immediately. See also Section 8.

## 7. Accuracy

All roots are evaluated as accurately as possible, but because of

found. After the failure has occurred, the remaining  $2*(n-n)$   
 $R$   
 elements of Z contain a large negative number (equal to  
 $-1/(X02AMF().\sqrt{2})$ ).

9. Example

To find the roots of the polynomial  $a_5 z^5 + a_4 z^4 + a_3 z^3 + a_2 z^2 + a_1 z + a_0 = 0$ ,  
 where  $a_0 = (5.0+6.0i)$ ,  $a_1 = (30.0+20.0i)$ ,  $a_2 = -(0.2+6.0i)$ ,  
 $a_3 = (50.0+100000.0i)$ ,  $a_4 = -(2.0-40.0i)$  and  $a_5 = (10.0+1.0i)$ .

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

CO2AGF(3NAG)      Foundation Library (12/10/92)      CO2AGF(3NAG)

CO2 -- Zeros of Polynomials      CO2AGF  
 CO2AGF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

CO2AGF finds all the roots of a real polynomial equation, using a variant of Laguerre's Method.

2. Specification

SUBROUTINE CO2AGF (A, N, SCALE, Z, W, IFAIL)  
 INTEGER            N, IFAIL  
 DOUBLE PRECISION A(N+1), Z(2,N), W(2\*(N+1))  
 LOGICAL            SCALE

3. Description

The routine attempts to find all the roots of the nth degree real polynomial equation

$$P(z) = a_0 z^n + a_1 z^{n-1} + a_2 z^{n-2} + \dots + a_{n-1} z + a_n = 0.$$

The roots are located using a modified form of Laguerre's Method, originally proposed by Smith [2].

The method of Laguerre [3] can be described by the iterative scheme

$$L(z)_k = z_k - z_k \frac{-n P(z)_k}{P'(z)_k + \sqrt{H(z)_k}},$$

where  $H(z)_k = (n-1) * [(n-1) * (P'(z)_k)^2 - n P(z)_k P''(z)_k]$ , and  $z_0$  is specified.

The sign in the denominator is chosen so that the modulus of the Laguerre step at  $z_k$ , viz.  $|L(z)_k|$ , is as small as possible. The method can be shown to be cubically convergent for isolated roots (real or complex) and linearly convergent for multiple roots. The routine generates a sequence of iterates  $z_1, z_2, z_3, \dots$ , such that  $|P(z_{k+1})| < |P(z_k)|$  and ensures that  $z_{k+1} + L(z)_k$  'roughly' lies inside a circular region of radius  $|F|$  about  $z_k$  known to contain a zero of  $P(z)$ ; that is,  $|L(z)_{k+1}| \leq |F|$ , where  $F$  denotes the Fejer bound (see Marden [1]) at the point  $z_k$ . Following Smith [2],  $F$  is taken to be  $\min(B, 1.445 * n * R)$ , where  $B$  is an upper bound for the magnitude of the smallest zero given by

$$B = 1.0001 * \min(\sqrt[n]{|L(z)_k|}, |r_1|, |a_n / a_0|),$$

$r_1$  is the zero of smaller magnitude of the quadratic equation

$$2(P''(z)_k / (2 * n * (n-1))) X^2 + 2(P'(z)_k / n) X + P(z)_k = 0$$

and the Cauchy lower bound R for the smallest zero is computed (using Newton's Method) as the positive root of the polynomial equation

$$|a_0|z^n + |a_1|z^{n-1} + |a_2|z^{n-2} + \dots + |a_{n-1}|z + |a_n| = 0.$$

Starting from the origin, successive iterates are generated according to the rule  $z_{k+1} = z_k + L(z_k)$  for  $k=1,2,3,\dots$  and  $L(z_k)$  is iterative procedure terminates if  $P(z_{k+1})$  is smaller in absolute value than the bound on the rounding error in  $P(z_{k+1})$  and the current iterate  $z_{k+1}$  is taken to be a zero of  $P(z)$  (as is its

conjugate  $\bar{z}$  if  $z$  is complex). The deflated polynomial  $\tilde{P}(z) = P(z)/(z - z_{k+1})$  of degree  $n-1$  if  $z_{k+1}$  is real  $\tilde{P}(z) = P(z)/((z - z_{k+1})(z - \bar{z}_{k+1}))$  of degree  $n-2$  if  $z_{k+1}$  is complex) is then formed, and the above procedure is repeated on the deflated polynomial until  $n < 3$ , whereupon the remaining roots are obtained via the 'standard' closed formulae for a linear ( $n = 1$ ) or quadratic ( $n = 2$ ) equation.

To obtain the roots of a quadratic polynomial, C02AJF(\*) can be used.

## 5. Parameters

- 1: A(N+1) -- DOUBLE PRECISION array Input  
 On entry: if A is declared with bounds (0:N), then A(i) must contain a  $a_i$  (i.e., the coefficient of  $z^{n-i}$ ), for  $i=0,1,\dots,n$ . Constraint: A(0) /= 0.0.
- 2: N -- INTEGER Input  
 On entry: the degree of the polynomial, n. Constraint: N >= 1.
- 3: SCALE -- LOGICAL Input  
 On entry: indicates whether or not the polynomial is to be scaled. See Section 8 for advice on when it may be preferable to set SCALE = .FALSE. and for a description of the scaling strategy. Suggested value: SCALE = .TRUE..
- 4: Z(2,N) -- DOUBLE PRECISION array Output  
 On exit: the real and imaginary parts of the roots are stored in Z(1,i) and Z(2,i) respectively, for  $i=1,2,\dots,n$ . Complex conjugate pairs of roots are stored in consecutive pairs of elements of Z; that is,  $Z(1,i+1) = Z(1,i)$  and  $Z(2,i+1) = -Z(2,i)$ .
- 5: W(2\*(N+1)) -- DOUBLE PRECISION array Workspace
- 6: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1  
 On entry A(0) = 0.0,  
 or N < 1.

IFAIL= 2  
 The iterative procedure has failed to converge. This error is very unlikely to occur. If it does, please contact NAG

immediately, as some basic assumption for the arithmetic has been violated. See also Section 8.

IFAIL= 3

Either overflow or underflow prevents the evaluation of P(z) near some of its zeros. This error is very unlikely to occur. If it does, please contact NAG immediately. See also Section 8.

7. Accuracy

All roots are evaluated as accurately as possible, but because of the inherent nature of the problem complete accuracy cannot be guaranteed.

8. Further Comments

If SCALE = .TRUE., then a scaling factor for the coefficients is chosen as a power of the base B of the machine so that the

largest coefficient in magnitude approaches  $THRESH = B^{EMAX-P}$ . Users should note that no scaling is performed if the largest coefficient in magnitude exceeds THRESH, even if SCALE = .TRUE.. (For definition of B, EMAX and P see the Chapter Introduction X02.)

However, with SCALE = .TRUE., overflow may be encountered when the input coefficients  $a_0, a_1, a_2, \dots, a_n$  vary widely in magnitude,

particularly on those machines for which  $B^{(4*P)}$  overflows. In such cases, SCALE should be set to .FALSE. and the coefficients scaled so that the largest coefficient in magnitude does not exceed  $B^{(EMAX-2*P)}$ .

Even so, the scaling strategy used in CO2AGF is sometimes insufficient to avoid overflow and/or underflow conditions. In such cases, the user is recommended to scale the independent variable (z) so that the disparity between the largest and smallest coefficient in magnitude is reduced. That is, use the routine to locate the zeros of the polynomial  $d*P(cz)$  for some suitable values of c and d. For example, if the original polynomial was  $P(z) = 2^{-100} z^{100} + 2^{20} z^{-10}$ , then choosing  $c = 2^{100}$  and  $d = 2^{20}$ , for instance, would yield the scaled polynomial  $1+z$ , which is well-behaved relative to overflow and underflow and has zeros which are 2 times those of P(z).

If the routine fails with IFAIL = 2 or 3, then the real and imaginary parts of any roots obtained before the failure occurred are stored in Z in the reverse order in which they were found. Let  $n$  denote the number of roots found before the failure

$Z(1,n)$  and  $Z(2,n)$  contain the real and imaginary parts of the 1st root found,  $Z(1,n-1)$  and  $Z(2,n-1)$  contain the real and imaginary parts of the 2nd root found, ...,  $Z(1,n)$  and  $Z(2,n)$  contain the real and imaginary parts of the  $n$ th root found. After the failure has occurred, the remaining  $2*(n-n)$  elements of Z contain a large negative number (equal to

$-1/(X02AMF().\sqrt{2})$ ).

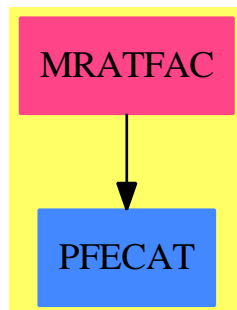

#### 9. Example

To find the roots of the 5th degree polynomial

$$z^5 + 2z^4 + 3z^3 + 4z^2 + 5z + 6 = 0.$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

— NagRootFindingPackage.help —

This package uses the NAG Library to calculate real zeros of continuous real functions of one or more variables. (Complex equations must be expressed in terms of the equivalent larger system of real equations.)

C05(3NAG)                    Foundation Library (12/10/92)                    C05(3NAG)

C05 -- Roots of One or More Transcendental Equations  
Introduction -- C05

Chapter C05  
 Roots of One or More Transcendental Equations

1. Scope of the Chapter

This chapter is concerned with the calculation of real zeros of continuous real functions of one or more variables. (Complex equations must be expressed in terms of the equivalent larger

system of real equations.)

## 2. Background to the Problems

The chapter divides naturally into two parts.

### 2.1. A Single Equation

The first deals with the real zeros of a real function of a single variable  $f(x)$ .

At present, there is only one routine with a simple calling sequence. This routine assumes that the user can determine an initial interval  $[a,b]$  within which the desired zero lies, that is  $f(a)*f(b)<0$ , and outside which all other zeros lie. The routine then systematically subdivides the interval to produce a final interval containing the zero. This final interval has a length bounded by the user's specified error requirements; the end of the interval where the function has smallest magnitude is returned as the zero. This routine is guaranteed to converge to a simple zero of the function. (Here we define a simple zero as a zero corresponding to a sign-change of the function.) The algorithm used is due to Bus and Dekker.

### 2.2. Systems of Equations

The routines in the second part of this chapter are designed to solve a set of nonlinear equations in  $n$  unknowns

$$f_i(x) = 0, \quad i=1,2,\dots,n, \quad x = (x_1, x_2, \dots, x_n)^T \quad (1)$$

where  $T$  stands for transpose.

It is assumed that the functions are continuous and differentiable so that the matrix of first partial derivatives of the functions, the Jacobian matrix  $J_{ij}(x) = \text{ddf} / \text{ddx}$  evaluated at the point  $x$ , exists, though it may not be possible to calculate it directly.

The functions  $f_i$  must be independent, otherwise there will be an infinity of solutions and the methods will fail. However, even when the functions are independent the solutions may not be unique. Since the methods are iterative, an initial guess at the solution has to be supplied, and the solution located will usually be the one closest to this initial guess.

- [4] Rabinowitz P (1970) Numerical Methods for Nonlinear Algebraic Equations. Gordon and Breach.

3. Recommendations on Choice and Use of Routines

3.1. Zeros of Functions of One Variable

There is only one routine (C05ADF) for solving a single nonlinear equation. This routine is designed for solving problems where the function  $f(x)$  whose zero is to be calculated, can be coded as a user-supplied routine.

C05ADF may only be used when the user can supply an interval  $[a,b]$  containing the zero, that is  $f(a)*f(b)<0$ .

3.2. Solution of Sets of Nonlinear Equations

The solution of a set of nonlinear equations

$$f_i(x_1, x_2, \dots, x_n) = 0, \quad i=1, 2, \dots, n \quad (2)$$

can be regarded as a special case of the problem of finding a minimum of a sum of squares

$$s(x) = \sum_{i=1}^m [f_i(x_1, x_2, \dots, x_n)]^2 \quad (m \geq n). \quad (3)$$

So the routines in Chapter E04 of the Library are relevant as well as the special nonlinear equations routines.

There are two routines (C05NBF and C05PBF) for solving a set of nonlinear equations. These routines require the  $f_i$  (and possibly  $i$

their derivatives) to be calculated in user-supplied routines. These should be set up carefully so the Library routines can work as efficiently as possible.

The main decision which has to be made by the user is whether to

ddf  
i

supply the derivatives ----. It is advisable to do so if

ddx  
j

possible, since the results obtained by algorithms which use derivatives are generally more reliable than those obtained by algorithms which do not use derivatives.

C05PBF requires the user to provide the derivatives, whilst C05NBF does not. C05NBF and C05PBF are easy-to-use routines. A routine, C05ZAF, is provided for use in conjunction with C05PBF to check the user-provided derivatives for consistency with the functions themselves. The user is strongly advised to make use of this routine whenever C05PBF is used.

Firstly, the calculation of the functions and their derivatives should be ordered so that cancellation errors are avoided. This is particularly important in a routine that uses these quantities to build up estimates of higher derivatives.

Secondly, scaling of the variables has a considerable effect on the efficiency of a routine. The problem should be designed so that the elements of  $x$  are of similar magnitude. The same comment applies to the functions, all the  $f_i$  should be of comparable

i

size.

The accuracy is usually determined by the accuracy parameters of the routines, but the following points may be useful:

- (i) Greater accuracy in the solution may be requested by choosing smaller input values for the accuracy parameters. However, if unreasonable accuracy is demanded, rounding errors may become important and cause a failure.
- (ii) Some idea of the accuracies of the  $x_i$  may be obtained by monitoring the progress of the routine to see how many figures remain unchanged during the last few iterations.
- (iii) An approximation to the error in the solution  $x$ , given by  $e$  where  $e$  is the solution to the set of linear equations

$$J(x)e = -f(x)$$

where  $f(x) = (f_1(x), f_2(x), \dots, f_n(x))^T$  (see Chapter F04).

(iv) If the functions  $f_i(x)$  are changed by small amounts  $(\epsilon_i)$ , for  $i=1,2,\dots,n$ , then the corresponding change in the solution  $x$  is given approximately by  $(\sigma)$ , where  $(\sigma)$  is the solution of the set of linear equations  $J(x)(\sigma) = -(\epsilon)$ , (see Chapter F04).

Thus one can estimate the sensitivity of  $x$  to any uncertainties in the specification of  $f_i(x)$ , for  $i=1,2,\dots,n$ .

C05 -- Roots of One or More Transcendental Equations      C05ADF  
 C05ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

C05ADF locates a zero of a continuous function in a given interval by a combination of the methods of linear interpolation, extrapolation and bisection.

### 2. Specification

```

SUBROUTINE C05ADF (A, B, EPS, ETA, F, X, IFAIL)
  INTEGER          IFAIL
  DOUBLE PRECISION A, B, EPS, ETA, F, X
  EXTERNAL         F
  
```

### 3. Description

The routine attempts to obtain an approximation to a simple zero of the function  $f(x)$  given an initial interval  $[a,b]$  such that  $f(a)*f(b) \leq 0$ . The zero is found by calls to C05AZF(\*) whose specification should be consulted for details of the method used.

The approximation  $x$  to the zero ( $\alpha$ ) is determined so that one or both of the following criteria are satisfied:

$$(i) |x - (\alpha)| < EPS,$$

$$(ii) |f(x)| < ETA.$$

### 4. References

None.

### 5. Parameters

- |    |                                                                                               |       |
|----|-----------------------------------------------------------------------------------------------|-------|
| 1: | A -- DOUBLE PRECISION<br>On entry: the lower bound of the interval, a.                        | Input |
| 2: | B -- DOUBLE PRECISION<br>On entry: the upper bound of the interval, b. Constraint: B<br>/= A. | Input |
| 3: | EPS -- DOUBLE PRECISION                                                                       | Input |

On entry: the absolute tolerance to which the zero is required (see Section 3). Constraint:  $\text{EPS} > 0.0$ .

4: ETA -- DOUBLE PRECISION Input  
 On entry: a value such that if  $|f(x)| < \text{ETA}$ ,  $x$  is accepted as the zero. ETA may be specified as 0.0 (see Section 7).

5: F -- DOUBLE PRECISION FUNCTION, supplied by the user. External Procedure  
 F must evaluate the function  $f$  whose zero is to be determined.

Its specification is:

DOUBLE PRECISION FUNCTION F (XX)  
 DOUBLE PRECISION XX

1: XX -- DOUBLE PRECISION Input  
 On entry: the point at which the function must be evaluated.

F must be declared as EXTERNAL in the (sub)program from which C05ADF is called. Parameters denoted as Input must not be changed by this procedure.

6: X -- DOUBLE PRECISION Output  
 On exit: the approximation to the zero.

7: IFAIL -- INTEGER Input/Output  
 Before entry, IFAIL must be assigned a value. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

Unless the routine detects an error (see Section 6), IFAIL contains 0 on exit.

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 On entry  $\text{EPS} \leq 0.0$ ,

or  $A = B$ ,

or  $F(A) * F(B) > 0.0$ .

IFAIL= 2  
 Too much accuracy has been requested in the computation, that is, EPS is too small for the computer being used. The final value of X is an accurate approximation to the zero.

IFAIL= 3

A change in sign of  $f(x)$  has been determined as occurring near the point defined by the final value of  $X$ . However, there is some evidence that this sign-change corresponds to a pole of  $f(x)$ .

IFAIL= 4

Indicates that a serious error has occurred in C05AZF(\*). Check all routine calls. Seek expert help.

#### 7. Accuracy

This depends on the value of EPS and ETA. If full machine accuracy is required, they may be set very small, resulting in an error exit with IFAIL = 2, although this may involve more iterations than a lesser accuracy. The user is recommended to set  $ETA = 0.0$  and to use EPS to control the accuracy, unless he has considerable knowledge of the size of  $f(x)$  for values of  $x$  near the zero.

#### 8. Further Comments

The time taken by the routine depends primarily on the time spent evaluating  $F$  (see Section 5).

If it is important to determine an interval of length less than EPS containing the zero, or if the function  $F$  is expensive to evaluate and the number of calls to  $F$  is to be restricted, then use of C05AZF(\*) is recommended. Use of C05AZF(\*) is also recommended when the structure of the problem to be solved does not permit a simple function  $F$  to be written: the reverse communication facilities of C05AZF(\*) are more flexible than the direct communication of  $F$  required by C05ADF.

#### 9. Example

The example program below calculates the zero of  $e^{-x}$  within the interval  $[0,1]$  to approximately 5 decimal places.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

C05NBF(3NAG)            Foundation Library (12/10/92)            C05NBF(3NAG)

C05 -- Roots of One or More Transcendental Equations            C05NBF

## C05NBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

C05NBF is an easy-to-use routine to find a solution of a system of nonlinear equations by a modification of the Powell hybrid method.

## 2. Specification

```

SUBROUTINE C05NBF (FCN, N, X, FVEC, XTOL, WA, LWA, IFAIL)
  INTEGER          N, LWA, IFAIL
  DOUBLE PRECISION X(N), FVEC(N), XTOL, WA(LWA)
  EXTERNAL         FCN

```

## 3. Description

The system of equations is defined as:

$$f(x_1, x_2, \dots, x_n) = 0, \text{ for } i=1, 2, \dots, n.$$

C05NBF is based upon the MINPACK routine HYBRD1 (More et al [1]). It chooses the correction at each step as a convex combination of the Newton and scaled gradient directions. Under reasonable conditions this guarantees global convergence for starting points far from the solution and a fast rate of convergence. The Jacobian is updated by the rank-1 method of Broyden. At the starting point the Jacobian is approximated by forward differences, but these are not used again until the rank-1 method fails to produce satisfactory progress. For more details see Powell [2].

## 5. Parameters

1: FCN -- SUBROUTINE, supplied by the user.

External Procedure

FCN must return the values of the functions  $f_i$  at a point  $x_i$ .

Its specification is:

```

SUBROUTINE FCN (N, X, FVEC, IFLAG)
  INTEGER      N, IFLAG
  DOUBLE PRECISION X(N), FVEC(N)

```

1: N -- INTEGER Input  
 On entry: the number of equations,  $n$ .

2: X(N) -- DOUBLE PRECISION array Input  
 On entry: the components of the point  $x$  at which the functions must be evaluated.

3: FVEC(N) -- DOUBLE PRECISION array Output  
 On exit: the function values  $f(x)$  (unless IFLAG is set to a negative value by FCN).

4: IFLAG -- INTEGER Input/Output  
 On entry: IFLAG > 0. On exit: in general, IFLAG should not be reset by FCN. If, however, the user wishes to terminate execution (perhaps because some illegal point  $X$  has been reached), then IFLAG should be set to a negative integer. This value will be returned through IFAIL.

FCN must be declared as EXTERNAL in the (sub)program from which C05NBF is called. Parameters denoted as Input must not be changed by this procedure.

2: N -- INTEGER Input  
 On entry: the number of equations,  $n$ . Constraint:  $N > 0$ .

3: X(N) -- DOUBLE PRECISION array Input/Output  
 On entry: an initial guess at the solution vector. On exit: the final estimate of the solution vector.

4: FVEC(N) -- DOUBLE PRECISION array Output  
 On exit: the function values at the final point,  $X$ .

5: XTOL -- DOUBLE PRECISION Input  
 On entry: the accuracy in  $X$  to which the solution is required. Suggested value: the square root of the machine precision. Constraint:  $XTOL \geq 0.0$ .

6: WA(LWA) -- DOUBLE PRECISION array Workspace

7: LWA -- INTEGER Input  
 On entry: the dimension of the array WA. Constraint:  
 $LWA \geq N \cdot (3 \cdot N + 13) / 2$ .

8: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not  
 familiar with this parameter (described in the Essential  
 Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see  
 Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are  
 output on the current error message unit (as defined by X04AAF).

IFAIL < 0

The user has set IFLAG negative in FCN. The value of IFAIL  
 will be the same as the user's setting of IFLAG.

IFAIL = 1

On entry  $N \leq 0$ ,

or  $XTOL < 0.0$ ,

or  $LWA < N \cdot (3 \cdot N + 13) / 2$ .

IFAIL = 2

There have been at least  $200 \cdot (N + 1)$  evaluations of FCN.  
 Consider restarting the calculation from the final point  
 held in X.

IFAIL = 3

No further improvement in the approximate solution X is  
 possible; XTOL is too small.

IFAIL = 4

The iteration is not making good progress. This failure exit  
 may indicate that the system does not have a zero, or that  
 the solution is very close to the origin (see Section 7).  
 Otherwise, rerunning C05NBF from a different starting point  
 may avoid the region of difficulty.

## 7. Accuracy

~

If  $x$  is the true solution, C05NBF tries to ensure that

$$\|x - \hat{x}\| \leq XTOL * \|x\|.$$

If this condition is satisfied with  $XTOL = 10^{-k}$ , then the larger components of  $x$  have  $k$  significant decimal digits. There is a danger that the smaller components of  $x$  may have large relative errors, but the fast rate of convergence of C05NBF usually avoids this possibility.

If  $XTOL$  is less than machine precision, and the above test is satisfied with the machine precision in place of  $XTOL$ , then the routine exits with  $IFAIL = 3$ .

Note: this convergence test is based purely on relative error, and may not indicate convergence if the solution is very close to the origin.

The test assumes that the functions are reasonably well behaved. If this condition is not satisfied, then C05NBF may incorrectly indicate convergence. The validity of the answer can be checked, for example, by rerunning C05NBF with a tighter tolerance.

#### 8. Further Comments

The time required by C05NBF to solve a given problem depends on  $n$ , the behaviour of the functions, the accuracy requested and the starting point. The number of arithmetic operations executed by

C05NBF to process each call of FCN is about  $11.5 * n^2$ . Unless FCN can be evaluated quickly, the timing of C05NBF will be strongly influenced by the time spent in FCN.

Ideally the problem should be scaled so that at the solution the function values are of comparable magnitude.

#### 9. Example

To determine the values  $x_1, \dots, x_9$  which satisfy the tridiagonal equations:

$$(3-2x_1)x_1 - 2x_2 = -1$$

$$-x_i - 1 + (3-2x_i)x_i - 2x_{i+1} = -1, \quad i=2,3,\dots,8$$

$$-x + (3-2x)x = -1.$$

8      9    9

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

C05PBF(3NAG)      Foundation Library (12/10/92)      C05PBF(3NAG)

C05 -- Roots of One or More Transcendental Equations      C05PBF  
 C05PBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

C05PBF is an easy-to-use routine to find a solution of a system of nonlinear equations by a modification of the Powell hybrid method. The user must provide the Jacobian.

2. Specification

```

SUBROUTINE C05PBF (FCN, N, X, FVEC, FJAC, LDFJAC, XTOL,
1                    WA, LWA, IFAIL)
INTEGER            N, LDFJAC, LWA, IFAIL
DOUBLE PRECISION X(N), FVEC(N), FJAC(LDFJAC,N), XTOL, WA
1                    (LWA)
EXTERNAL           FCN
    
```

3. Description

The system of equations is defined as:

$$f(x_1, x_2, \dots, x_n) = 0, \quad i=1, 2, \dots, n.$$

C05PBF is based upon the MINPACK routine HYBRJ1 (More et al [1]). It chooses the correction at each step as a convex combination of the Newton and scaled gradient directions. Under reasonable conditions this guarantees global convergence for starting points far from the solution and a fast rate of convergence. The Jacobian is updated by the rank-1 method of Broyden. At the starting point the Jacobian is calculated, but it is not recalculated until the rank-1 method fails to produce satisfactory progress. For more details see Powell [2].

## 5. Parameters

1: FCN -- SUBROUTINE, supplied by the user.

External Procedure

Depending upon the value of IFLAG, FCN must either return the values of the functions  $f_i$  at a point  $x$  or return the

Jacobian at  $x$ .

Its specification is:

```

SUBROUTINE FCN (N, X, FVEC, FJAC, LDFJAC, IFLAG)
INTEGER          N, LDFJAC, IFLAG
DOUBLE PRECISION X(N), FVEC(N), FJAC(LDFJAC,N)

```

1: N -- INTEGER Input  
 On entry: the number of equations,  $n$ .

2: X(N) -- DOUBLE PRECISION array Input  
 On entry: the components of the point  $x$  at which the functions or the Jacobian must be evaluated.

3: FVEC(N) -- DOUBLE PRECISION array Output  
 On exit: if IFLAG = 1 on entry, FVEC must contain the function values  $f_i(x)$  (unless IFLAG is set to a negative value by FCN). If IFLAG = 2 on entry, FVEC must not be changed.

4: FJAC(LDFJAC,N) -- DOUBLE PRECISION array Output  
 On exit: if IFLAG = 2 on entry, FJAC( $i,j$ ) must contain  $\frac{df_i}{dx_j}$  the value of  $\frac{df_i}{dx_j}$  at the point  $x$ , for  $i,j=1,2,\dots,n$  (unless IFLAG is set to a negative value by FCN).

If IFLAG = 1 on entry, FJAC must not be changed.

- 5: LDFJAC -- INTEGER Input  
 On entry: the first dimension of FJAC.
- 6: IFLAG -- INTEGER Input/Output  
 On entry: IFLAG = 1 or 2:  
     if IFLAG = 1, FVEC is to be updated;  
  
     if IFLAG = 2, FJAC is to be updated.  
 On exit: in general, IFLAG should not be reset by FCN.  
 If, however, the user wishes to terminate execution  
 (perhaps because some illegal point x has been reached)  
 then IFLAG should be set to a negative integer. This  
 value will be returned through IFAIL.  
 FCN must be declared as EXTERNAL in the (sub)program  
 from which C05PBF is called. Parameters denoted as  
 Input must not be changed by this procedure.
- 2: N -- INTEGER Input  
 On entry: the number of equations, n. Constraint:  $N > 0$ .
- 3: X(N) -- DOUBLE PRECISION array Input/Output  
 On entry: an initial guess at the solution vector. On  
 exit: the final estimate of the solution vector.
- 4: FVEC(N) -- DOUBLE PRECISION array Output  
 On exit: the function values at the final point, X.
- 5: FJAC(LDFJAC,N) -- DOUBLE PRECISION array Output  
 On exit: the orthogonal matrix Q produced by the QR  
 factorization of the final approximate Jacobian.
- 6: LDFJAC -- INTEGER Input  
 On entry:  
 the first dimension of the array FJAC as declared in the  
 (sub)program from which C05PBF is called.  
 Constraint:  $LDFJAC \geq N$ .
- 7: XTOL -- DOUBLE PRECISION Input  
 On entry: the accuracy in X to which the solution is  
 required. Suggested value: the square root of the machine  
 precision. Constraint:  $XTOL \geq 0.0$ .
- 8: WA(LWA) -- DOUBLE PRECISION array Workspace
- 9: LWA -- INTEGER Input  
 On entry: the dimension of the array WA. Constraint:  
 $LWA \geq N*(N+13)/2$ .
- 10: IFAIL -- INTEGER Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL < 0

A negative value of IFAIL indicates an exit from C05PBF because the user has set IFLAG negative in FCN. The value of IFAIL will be the same as the user's setting of IFLAG.

IFAIL = 1

On entry  $N \leq 0$ ,  
 or  $LDFJAC < N$ ,  
 or  $XTOL < 0.0$ ,  
 or  $LWA < N*(N+13)/2$ .

IFAIL = 2

There have been  $100*(N+1)$  evaluations of the functions. Consider restarting the calculation from the final point held in X.

IFAIL = 3

No further improvement in the approximate solution X is possible; XTOL is too small.

IFAIL = 4

The iteration is not making good progress. This failure exit may indicate that the system does not have a zero or that the solution is very close to the origin (see Section 7). Otherwise, rerunning C05PBF from a different starting point may avoid the region of difficulty.

## 7. Accuracy

If  $x$  is the true solution, C05PBF tries to ensure that

$$\frac{\|x-x\|}{2} \leq XTOL * \frac{\|x\|}{2} .$$

-k

If this condition is satisfied with  $XTOL=10^{-k}$ , then the larger components of  $x$  have  $k$  significant decimal digits. There is a danger that the smaller components of  $x$  may have large relative errors, but the fast rate of convergence of C05PBF usually avoids the possibility.

If  $XTOL$  is less than machine precision and the above test is satisfied with the machine precision in place of  $XTOL$ , then the routine exits with  $IFAIL = 3$ .

Note: this convergence test is based purely on relative error, and may not indicate convergence if the solution is very close to the origin.

The test assumes that the functions and Jacobian are coded consistently and that the functions are reasonably well behaved. If these conditions are not satisfied then C05PBF may incorrectly indicate convergence. The coding of the Jacobian can be checked using C05ZAF. If the Jacobian is coded correctly, then the validity of the answer can be checked by rerunning C05PBF with a tighter tolerance.

#### 8. Further Comments

The time required by C05PBF to solve a given problem depends on  $n$ , the behaviour of the functions, the accuracy requested and the starting point. The number of arithmetic operations executed by

C05PBF is about  $11.5 * n^2$  to process each evaluation of the

functions and about  $1.3 * n^3$  to process each evaluation of the Jacobian. Unless FCN can be evaluated quickly, the timing of C05PBF will be strongly influenced by the time spent in FCN.

Ideally the problem should be scaled so that, at the solution, the function values are of comparable magnitude.

#### 9. Example

To determine the values  $x_1, \dots, x_9$  which satisfy the tridiagonal equations:

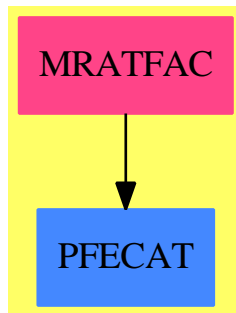

$$(3-2x_1)x_1 - 2x_2 = -1$$

$$-x_{i-1} + (3-2x_i)x_i - 2x_{i+1} = -1, \quad i=2,3,\dots,8.$$

$$-x_8 + (3-2x_9)x_9 = -1.$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

### NagRootFindingPackage (NAGC05)

#### Exports:

— NagSeriesSummationPackage.help —

This package uses the NAG Library to calculate the discrete Fourier transform of a sequence of real or complex data values, and applies it to calculate convolutions and correlations.

C06(3NAG)

Foundation Library (12/10/92)

C06(3NAG)

C06 -- Summation of Series

Introduction -- C06

Chapter C06  
Summation of Series

1. Scope of the Chapter

This chapter is concerned with calculating the discrete Fourier transform of a sequence of real or complex data values, and applying it to calculate convolutions and correlations.

2. Background to the Problems

2.1. Discrete Fourier Transforms

2.1.1. Complex transforms

Most of the routines in this chapter calculate the finite discrete Fourier transform (DFT) of a sequence of  $n$  complex numbers  $z_j$ , for  $j=0,1,\dots,n-1$ . The transform is defined by:

$$\hat{z}_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} z_j \exp(-i \frac{2(\pi)jk}{n}) \tag{1}$$

for  $k=0,1,\dots,n-1$ . Note that equation (1) makes sense for all integral  $k$  and with this extension  $\hat{z}_k$  is periodic with period  $n$ , i.e.  $\hat{z}_k = \hat{z}_{k+n}$ , and in particular  $\hat{z}_{-k} = \hat{z}_{n-k}$ .

If we write  $z_j = x_j + iy_j$  and  $\hat{z}_k = a_k + ib_k$ , then the definition of  $\hat{z}_k$  may be written in terms of sines and cosines as:

$$a_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} (x_j \cos(\frac{2(\pi)jk}{n}) + y_j \sin(\frac{2(\pi)jk}{n}))$$

$$b_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} (y_j \cos(\frac{2(\pi)jk}{n}) - x_j \sin(\frac{2(\pi)jk}{n})).$$

The original data values  $z_j$  may conversely be recovered from the

transform  $\hat{z}_k$  by an inverse discrete Fourier transform:

$$\hat{z}_j = \frac{1}{\sqrt{n}} \sum_{k=0}^{n-1} \hat{z}_k \exp(+i \frac{2(\pi)jk}{n}) \quad (2)$$

for  $j=0,1,\dots,n-1$ . If we take the complex conjugate of (2), we

find that the sequence  $\hat{z}_j$  is the DFT of the sequence  $\hat{z}_k$ . Hence

the inverse DFT of the sequence  $\hat{z}_k$  may be obtained by: taking the

complex conjugates of the  $\hat{z}_k$ ; performing a DFT; and taking the complex conjugates of the result.

Notes: definitions of the discrete Fourier transform vary. Sometimes (2) is used as the definition of the DFT, and (1) as

the definition of the inverse. Also the scale-factor of  $1/\sqrt{n}$  may be omitted in the definition of the DFT, and replaced by  $1/n$  in the definition of the inverse.

### 2.1.2. Real transforms

If the original sequence is purely real valued, i.e.  $z_j = x_j$ , then

$$\hat{z}_k = a_k + ib_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} x_j \exp(-i \frac{2(\pi)jk}{n})$$

and  $\hat{z}_{n-k}$  is the complex conjugate of  $\hat{z}_k$ . Thus the DFT of a real sequence is a particular type of complex sequence, called a Hermitian sequence, or half-complex or conjugate symmetric with the properties:

$$a_{n-k} = a_k, \quad b_{n-k} = -b_k \quad \text{and, if } n \text{ is even, } b_{n/2} = 0.$$

Thus a Hermitian sequence of  $n$  complex data values can be represented by only  $n$ , rather than  $2n$ , independent real values. This can obviously lead to economies in storage, the following scheme being used in this chapter: the real parts  $a_k$  for

$0 \leq k \leq n/2$  are stored in normal order in the first  $n/2+1$  locations of an array  $X$  of length  $n$ ; the corresponding non-zero imaginary parts are stored in reverse order in the remaining locations of  $X$ . In other words, if  $X$  is declared with bounds  $(0:n-1)$  in the

user's (sub)program, the real and imaginary parts of  $z_k$  are

stored as follows:

|          | if $n=2s$ | if $n=2s-1$ |
|----------|-----------|-------------|
| $X(0)$   | a<br>0    | a<br>0      |
| $X(1)$   | a<br>1    | a<br>1      |
| $X(2)$   | a<br>2    | a<br>2      |
| .        | .         | .           |
| .        | .         | .           |
| .        | .         | .           |
| $X(s-1)$ | a<br>s-1  | a<br>s-1    |
| $X(s)$   | a<br>s    | b<br>s-1    |
| $X(s+1)$ | b<br>s-1  | b<br>s-2    |
| .        | .         | .           |
| .        | .         | .           |
| .        | .         | .           |
| $X(n-2)$ | b         | b           |

$$X(n-1) = \frac{b}{1} \quad \frac{b}{1}$$

$$\text{Hence } x_j = \frac{1}{\sqrt{n}} \sum_{k=0}^{n/2-1} \left( a \cos\left(\frac{2(\pi)jk}{n}\right) - b \sin\left(\frac{2(\pi)jk}{n}\right) + a \right)$$

where  $a = 0$  if  $n$  is odd.

2.1.3. Fourier integral transforms

The usual application of the discrete Fourier transform is that of obtaining an approximation of the Fourier integral transform

$$F(s) = \int_{-\infty}^{+\infty} f(t) \exp(-i2(\pi)st) dt$$

when  $f(t)$  is negligible outside some region  $(0,c)$ . Dividing the region into  $n$  equal intervals we have

$$F(s) \sim \frac{1}{n} \sum_{j=0}^{n-1} f \exp(-i2(\pi)sjc/n)$$

and so

$$F \sim \frac{1}{n} \sum_{j=0}^{n-1} f \exp(-i2(\pi)jk/n)$$

for  $k=0,1,\dots,n-1$ , where  $f = f(jc/n)$  and  $F = F(k/c)$ .

Hence the discrete Fourier transform gives an approximation to the Fourier integral transform in the region  $s=0$  to  $s=n/c$ .

If the function  $f(t)$  is defined over some more general interval  $(a,b)$ , then the integral transform can still be approximated by the discrete transform provided a shift is applied to move the point  $a$  to the origin.

2.1.4. Convolutions and correlations

One of the most important applications of the discrete Fourier transform is to the computation of the discrete convolution or correlation of two vectors  $x$  and  $y$  defined (as in Brigham [1]) by:

$$\begin{aligned} & \begin{array}{c} n-1 \\ -- \\ \text{convolution: } z = \sum_{k=0}^{n-1} x_k y_{k-j} \end{array} \\ & \begin{array}{c} n-1 \\ -- \\ \text{correlation: } w = \sum_{k=0}^{n-1} x_k y_{k+j} \end{array} \end{aligned}$$

(Here  $x$  and  $y$  are assumed to be periodic with period  $n$ .)

Under certain circumstances (see Brigham [1]) these can be used as approximations to the convolution or correlation integrals defined by:

$$z(s) = \int_{-\infty}^{+\infty} x(t)y(s-t)dt$$

and

$$w(s) = \int_{-\infty}^{+\infty} x(t)y(s+t)dt, \quad -\infty < s < +\infty.$$

For more general advice on the use of Fourier transforms, see Hamming [2]; more detailed information on the fast Fourier transform algorithm can be found in Van Loan [3] and Brigham [1].

### 3. Recommendations on Choice and Use of Routines

#### 3.1. One-dimensional Fourier Transforms

The choice of routine is determined first of all by whether the data values constitute a real, Hermitian or general complex sequence. It is wasteful of time and storage to use an inappropriate routine.

Two groups, each of three routines, are provided

|                           | Group 1 | Group 2 |
|---------------------------|---------|---------|
| Real sequences            | C06EAF  | C06FPF  |
| Hermitian sequences       | C06EBF  | C06FQF  |
| General complex sequences | C06ECF  | C06FRF  |

Group 1 routines each compute a single transform of length  $n$ , without requiring any extra working storage. The Group 1 routines impose some restrictions on the value of  $n$ , namely that no prime factor of  $n$  may exceed 19 and the total number of prime factors (including repetitions) may not exceed 20 (though the latter restriction only becomes relevant when  $n > 10^6$ ).

Group 2 routines are designed to perform several transforms in a single call, all with the same value of  $n$ . They do however require more working storage. Even on scalar processors, they may be somewhat faster than repeated calls to Group 1 routines because of reduced overheads and because they pre-compute and store the required values of trigonometric functions. Group 2 routines impose no practical restrictions on the value of  $n$ ; however the fast Fourier transform algorithm ceases to be 'fast' if applied to values of  $n$  which cannot be expressed as a product of small prime factors. All the above routines are particularly efficient if the only prime factors of  $n$  are 2, 3 or 5.

If extensive use is to be made of these routines, users who are

concerned about efficiency are advised to conduct their own timing tests.

To compute inverse discrete Fourier transforms the above routines should be used in conjunction with the utility routines C06GBF, C06GCF and C06GQF which form the complex conjugate of a Hermitian or general sequence of complex data values.

### 3.2. Multi-dimensional Fourier Transforms

C06FUF computes a 2-dimensional discrete Fourier transform of a 2-dimensional sequence of complex data values. This is defined by

$$z_{k_1 k_2} = \frac{1}{\sqrt{n_1 n_2}} \sum_{j_1=0}^{n_1-1} \sum_{j_2=0}^{n_2-1} z_{j_1 j_2} \exp(-i \frac{2\pi j_1 k_1}{n_1}) \exp(-i \frac{2\pi j_2 k_2}{n_2})$$

### 3.3. Convolution and Correlation

C06EKF computes either the discrete convolution or the discrete correlation of two real vectors.

### 3.4. Index

|                                           |        |

SUBROUTINE C06EAF (X, N, IFAIL)
INTEGER          N, IFAIL
DOUBLE PRECISION X(N)
    
```

3. Description

Given a sequence of  $n$  real data values  $x_j$ , for  $j=0,1,\dots,n-1$ , this routine calculates their discrete Fourier transform defined by:

$$z_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} x_j \exp(-i \frac{2(\pi)jk}{n}), \quad k=0,1,\dots,n-1.$$

(Note the scale factor of  $\frac{1}{\sqrt{n}}$  in this definition.) The

transformed values  $z_k$  are complex, but they form a Hermitian sequence (i.e.,  $z_{n-k}$  is the complex conjugate of  $z_k$ ), so they are completely determined by  $n$  real numbers (see also the Chapter Introduction).

To compute the inverse discrete Fourier transform defined by:

$$w_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} x_j \exp(+i \frac{2(\pi)jk}{n}),$$

this routine should be followed by a call of C06GBF to form the complex conjugates of the  $z_k$ .

The routine uses the fast Fourier transform (FFT) algorithm (Brigham [1]). There are some restrictions on the value of  $n$  (see Section 5).

4. References

- [1] Brigham E O (1973) The Fast Fourier Transform. Prentice-Hall.

#### 5. Parameters

- 1: X(N) -- DOUBLE PRECISION array Input/Output  
 On entry: if X is declared with bounds (0:N-1) in the (sub) program from which C06EAF is called, then X(j) must contain  $x_j$ , for  $j=0,1,\dots,n-1$ . On exit: the discrete Fourier transform stored in Hermitian form. If the components of the transform  $z_k$  are written as  $a_k + ib_k$ , and if X is declared with bounds (0:N-1) in the (sub)program from which C06EAF is called, then for  $0 \leq k \leq n/2$ ,  $a_k$  is contained in X(k), and for  $1 \leq k \leq (n-1)/2$ ,  $b_k$  is contained in X(n-k). (See also Section 2.1.2 of the Chapter Introduction, and the Example Program.)
- 2: N -- INTEGER Input  
 On entry: the number of data values, n. The largest prime factor of N must not exceed 19, and the total number of prime factors of N, counting repetitions, must not exceed 20. Constraint:  $N > 1$ .
- 3: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

- IFAIL= 1  
 At least one of the prime factors of N is greater than 19.
- IFAIL= 2  
 N has more than 20 prime factors.
- IFAIL= 3  
 $N \leq 1$ .

#### 7. Accuracy

Some indication of accuracy can be obtained by performing a subsequent inverse transform and comparing the results with the original sequence (in exact arithmetic they would be identical).

8. Further Comments

The time taken by the routine is approximately proportional to  $n \cdot \log n$ , but also depends on the factorization of  $n$ . The routine is somewhat faster than average if the only prime factors of  $n$  are 2, 3 or 5; and fastest of all if  $n$  is a power of 2.

On the other hand, the routine is particularly slow if  $n$  has several unpaired prime factors, i.e., if the 'square-free' part of  $n$  has several factors. For such values of  $n$ , routine C06FAF(\*) (which requires an additional  $n$  elements of workspace) is considerably faster.

9. Example

This program reads in a sequence of real data values, and prints their discrete Fourier transform (as computed by C06EAF), after expanding it from Hermitian form into a full complex sequence.

It then performs an inverse transform using C06GBF and C06EBF, and prints the sequence so obtained alongside the original data values.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

 C06EBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

C06EBF calculates the discrete Fourier transform of a Hermitian sequence of  $n$  complex data values. (No extra workspace required.)

2. Specification

```

SUBROUTINE C06EBF (X, N, IFAIL)
INTEGER          N, IFAIL
DOUBLE PRECISION X(N)

```

### 3. Description

Given a Hermitian sequence of  $n$  complex data values  $z_j$  (i.e., a sequence such that  $z_0$  is real and  $z_j$  is the complex conjugate of  $z_{n-j}$ , for  $j=1,2,\dots,n-1$ ) this routine calculates their discrete Fourier transform defined by:

$$\hat{x}_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} z_j \exp(-i \frac{2(\pi)jk}{n}), \quad k=0,1,\dots,n-1.$$

(Note the scale factor of  $\frac{1}{\sqrt{n}}$  in this definition.) The

transformed values  $\hat{x}_k$  are purely real (see also the the Chapter Introduction).

To compute the inverse discrete Fourier transform defined by:

$$\hat{y}_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} z_j \exp(+i \frac{2(\pi)jk}{n}),$$

this routine should be preceded by a call of C06GBF to form the complex conjugates of the  $z_j$ .

The routine uses the fast Fourier transform (FFT) algorithm (Brigham [1]). There are some restrictions on the value of  $n$  (see Section 5).

Hall.

### 5. Parameters

- 1: X(N) -- DOUBLE PRECISION array Input/Output  
 On entry: the sequence to be transformed stored in Hermitian form. If the data values  $z_j$  are written as  $x_j + iy_j$ , and if X is declared with bounds (0:N-1) in the subroutine from which C06EBF is called, then for  $0 \leq j \leq n/2$ ,  $x_j$  is contained in X(j), and for  $1 \leq j \leq (n-1)/2$ ,  $y_j$  is contained in X(n-j). (See also Section 2.1.2 of the Chapter Introduction and the Example Program.) On exit: the components of the discrete Fourier transform  $\hat{x}_k$ . If X is declared with bounds (0:N-1) in the (sub)program from which C06EBF is called, then  $\hat{x}_k$  is stored in X(k), for  $k=0,1,\dots,n-1$ .
- 2: N -- INTEGER Input  
 On entry: the number of data values, n. The largest prime factor of N must not exceed 19, and the total number of prime factors of N, counting repetitions, must not exceed 20. Constraint:  $N > 1$ .
- 3: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

At least one of the prime factors of N is greater than 19.

IFAIL= 2

N has more than 20 prime factors.

IFAIL= 3

$N \leq 1$ .

C06ECF calculates the discrete Fourier transform of a sequence of n complex data values. (No extra workspace required.)

2. Specification

```

SUBROUTINE C06ECF (X, Y, N, IFAIL)
INTEGER          N, IFAIL
DOUBLE PRECISION X(N), Y(N)
    
```

3. Description

Given a sequence of n complex data values  $z_j$ , for  $j=0,1,\dots,n-1$ , this routine calculates their discrete Fourier transform defined by:

$$z_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} z_j \exp(-i \frac{2(\pi)jk}{n}), \quad k=0,1,\dots,n-1.$$

(Note the scale factor of  $\frac{1}{\sqrt{n}}$  in this definition.)

$$\sqrt{n}$$

To compute the inverse discrete Fourier transform defined by:

$$w_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} z_j \exp(+i \frac{2(\pi)jk}{n}),$$

this routine should be preceded and followed by calls of C06GCF

to form the complex conjugates of the  $z_j$  and the  $z_k$ .

The routine uses the fast Fourier transform (FFT) algorithm (Brigham [1]). There are some restrictions on the value of n (see Section 5).

4. References

[1] Brigham E O (1973) The Fast Fourier Transform. Prentice-Hall.

## 5. Parameters

- 1: X(N) -- DOUBLE PRECISION array Input/Output  
 On entry: if X is declared with bounds (0:N-1) in the (sub) program from which C06ECF is called, then X(j) must contain  $x_j$ , the real part of  $z_j$ , for  $j=0,1,\dots,n-1$ . On exit: the real parts  $a_k$  of the components of the discrete Fourier transform. If X is declared with bounds (0:N-1) in the (sub) program from which C06ECF is called, then  $a_k$  is contained in X(k), for  $k=0,1,\dots,n-1$ .
- 2: Y(N) -- DOUBLE PRECISION array Input/Output  
 On entry: if Y is declared with bounds (0:N-1) in the (sub) program from which C06ECF is called, then Y(j) must contain  $y_j$ , the imaginary part of  $z_j$ , for  $j=0,1,\dots,n-1$ . On exit: the imaginary parts  $b_k$  of the components of the discrete Fourier transform. If Y is declared with bounds (0:N-1) in the (sub)program from which C06ECF is called, then  $b_k$  is contained in Y(k), for  $k=0,1,\dots,n-1$ .
- 3: N -- INTEGER Input  
 On entry: the number of data values, n. The largest prime factor of N must not exceed 19, and the total number of prime factors of N, counting repetitions, must not exceed 20. Constraint:  $N > 1$ .
- 4: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

At least one of the prime factors of N is greater than 19.

IFAIL= 2

N has more than 20 prime factors.

real vectors of period  $n$ . No extra workspace is required.

## 2. Specification

```

SUBROUTINE C06EKF (JOB, X, Y, N, IFAIL)
  INTEGER          JOB, N, IFAIL
  DOUBLE PRECISION X(N), Y(N)

```

## 3. Description

This routine computes:

if  $JOB = 1$ , the discrete convolution of  $x$  and  $y$ , defined by:

$$z_k = \sum_{j=0}^{n-1} x_j y_{k-j} \quad ;$$

if  $JOB = 2$ , the discrete correlation of  $x$  and  $y$  defined by:

$$w_k = \sum_{j=0}^{n-1} x_j y_{k+j} .$$

Here  $x$  and  $y$  are real vectors, assumed to be periodic, with period  $n$ , i.e.,  $x_j = x_{j+n} = x_{j+2n} = \dots$ ;  $z$  and  $w$  are then also periodic with period  $n$ .

Note: this usage of the terms 'convolution' and 'correlation' is taken from Brigham [1]. The term 'convolution' is sometimes used to denote both these computations.

If  $\hat{x}$ ,  $\hat{y}$ ,  $\hat{z}$  and  $\hat{w}$  are the discrete Fourier transforms of these sequences,

$$\hat{x}_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} x_j \exp(-i \frac{2(\pi)jk}{n}), \text{ etc,}$$

$$\text{then } \hat{z}_k = \sqrt{n} \hat{x}_k \hat{y}_k$$

$$\text{and } w_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} \bar{x}_j y_{k-j}$$

(the bar denoting complex conjugate).

This routine calls the same auxiliary routines as C06EAF and C06EBF to compute discrete Fourier transforms, and there are some restrictions on the value of n.

4. References

- [1] Brigham E O (1973) The Fast Fourier Transform. Prentice-Hall.

5. Parameters

- 1: JOB -- INTEGER Input  
 On entry: the computation to be performed:  
     n-1  
     --  
     if JOB = 1,  $z_k = \sum_{j=0}^{n-1} x_j y_{k-j}$  (convolution);  
     j=0  
     n-1  
     --  
     if JOB = 2,  $w_k = \sum_{j=0}^{n-1} x_j y_{k+j}$  (correlation).  
     j=0  
 Constraint: JOB = 1 or 2.
- 2: X(N) -- DOUBLE PRECISION array Input/Output  
 On entry: the elements of one period of the vector x. If X is declared with bounds (0:N-1) in the (sub)program from which C06EKF is called, then X(j) must contain  $x_j$ , for  $j=0,1,\dots,n-1$ . On exit: the corresponding elements of the discrete convolution or correlation.
- 3: Y(N) -- DOUBLE PRECISION array Input/Output  
 On entry: the elements of one period of the vector y. If Y is declared with bounds (0:N-1) in the (sub)program from which C06EKF is called, then Y(j) must contain  $y_j$ , for  $j=0,1,\dots,n-1$ . On exit: the discrete Fourier transform of the convolution or correlation returned in the array X; the

transform is stored in Hermitian form, exactly as described in the document C06EAF.

4: N -- INTEGER Input  
 On entry: the number of values,  $n$ , in one period of the vectors  $X$  and  $Y$ . The largest prime factor of  $N$  must not exceed 19, and the total number of prime factors of  $N$ , counting repetitions, must not exceed 20. Constraint:  $N > 1$ .

5: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 At least one of the prime factors of  $N$  is greater than 19.

IFAIL= 2  
 $N$  has more than 20 prime factors.

IFAIL= 3  
 $N \leq 1$ .

IFAIL= 4  
 JOB  $\neq$  1 or 2.

#### 7. Accuracy

The results should be accurate to within a small multiple of the machine precision.

#### 8. Further Comments

The time taken by the routine is approximately proportional to  $n \cdot \log n$ , but also depends on the factorization of  $n$ . The routine is faster than average if the only prime factors are 2, 3 or 5; and fastest of all if  $n$  is a power of 2.

The routine is particularly slow if  $n$  has several unpaired prime factors, i.e., if the 'square free' part of  $n$  has several factors. For such values of  $n$ , routine C06FKF(\*) is considerably faster (but requires an additional workspace of  $n$  elements).

1

(Note the scale factor --- in this definition.)

$$\sqrt{n}$$

The transformed values  $z_k^{\hat{p}}$  are complex, but for each value of  $p$

the  $z_k^{\hat{p}}$  form a Hermitian sequence (i.e.,  $z_k^{\hat{p}}$  is the complex conjugate of  $z_{n-k}^{\hat{p}}$ ), so they are completely determined by  $mn$  real

numbers (see also the Chapter Introduction).

The discrete Fourier transform is sometimes defined using a positive sign in the exponential term:

$$z_k^{\hat{p}} = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} x_j \exp(+i \frac{2(\pi)jk}{n}).$$

To compute this form, this routine should be followed by a call to C06GQF to form the complex conjugates of the  $z_k^{\hat{p}}$ .

The routine uses a variant of the fast Fourier transform (FFT) algorithm (Brigham [1]) known as the Stockham self-sorting algorithm, which is described in Temperton [2]. Special coding is provided for the factors 2, 3, 4, 5 and 6. This routine is designed to be particularly efficient on vector processors, and it becomes especially fast as  $M$ , the number of transforms to be computed in parallel, increases.

#### 5. Parameters

1: M -- INTEGER

Input

in and re-used without the need for a call with INIT equal to 'I'. The routine carries out a simple test to check that the current value of n is consistent with the array TRIG. Constraint: INIT = 'I', 'S' or 'R'.

5: TRIG(2\*N) -- DOUBLE PRECISION array                   Input/Output  
On entry: if INIT = 'S' or 'R', TRIG must contain the required coefficients calculated in a previous call of the routine. Otherwise TRIG need not be set. On exit: TRIG contains the required coefficients (computed by the routine if INIT = 'I').

6: WORK(M\*N) -- DOUBLE PRECISION array                   Workspace

7: IFAIL -- INTEGER                                        Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1  
On entry  $M < 1$ .

IFAIL= 2  
 $N < 1$ .

IFAIL= 3  
INIT is not one of 'I', 'S' or 'R'.

IFAIL= 4  
INIT = 'S', but none of C06FPF, C06FQF or C06FRF has previously been called.

IFAIL= 5  
INIT = 'S' or 'R', but the array TRIG and the current value of N are inconsistent.

## 7. Accuracy

Some indication of accuracy can be obtained by performing a

Given  $m$  Hermitian sequences of  $n$  complex data values  $z_j^p$ , for  $j=0,1,\dots,n-1$ ;  $p=1,2,\dots,m$ , this routine simultaneously calculates the Fourier transforms of all the sequences defined by:

$$x_k^p = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} z_j^p \exp(-i \frac{2(\pi)jk}{n}), \quad k=0,1,\dots,n-1; \quad p=1,2,\dots,m.$$

(Note the scale factor  $\frac{1}{\sqrt{n}}$  in this definition.)

$\sqrt{n}$

The transformed values are purely real (see also the Chapter Introduction).

The discrete Fourier transform is sometimes defined using a positive sign in the exponential term

$$x_k^p = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} z_j^p \exp(+i \frac{2(\pi)jk}{n}).$$

To compute this form, this routine should be preceded by a call to C06GQF to form the complex conjugates of the  $z_j^p$ .

The routine uses a variant of the fast Fourier transform (FFT) algorithm (Brigham [1]) known as the Stockham self-sorting algorithm, which is described in Temperton [2]. Special code is included for the factors 2, 3, 4, 5 and 6. This routine is designed to be particularly efficient on vector processors, and it becomes especially fast as  $m$ , the number of transforms to be computed in parallel, increases.

5. Parameters

1: M -- INTEGER Input  
 On entry: the number of sequences to be transformed, m.  
 Constraint: M >= 1.

2: N -- INTEGER Input  
 On entry: the number of data values in each sequence, n.  
 Constraint: N >= 1.

3: X(M,N) -- DOUBLE PRECISION array Input/Output  
 On entry: the data must be stored in X as if in a two-dimensional array of dimension (1:M,0:N-1); each of the m sequences is stored in a row of the array in Hermitian form.

$$z_j^p \text{ are written as } x_j^p + iy_j^p, \text{ then for}$$

$$0 \leq j \leq n/2, x_j^p \text{ is contained in } X(p,j), \text{ and for } 1 \leq j \leq (n-1)/2,$$

$$y_j^p \text{ is contained in } X(p,n-j).$$

(See also Section 2.1.2 of the Chapter Introduction.) On exit: the components of the m discrete Fourier transforms, stored as if in a two-dimensional array of dimension (1:M,0:N-1). Each of the m transforms is stored as a row of the array, overwriting the corresponding original sequence. If the n components of the

$$\text{discrete Fourier transform are denoted by } x_k^p, \text{ for}$$

k=0,1,...,n-1, then the mn elements of the array X contain the values

$$x_{00}^{p1}, x_{01}^{p1}, \dots, x_{0n-1}^{p1}, x_{10}^{p1}, x_{11}^{p1}, \dots, x_{1n-1}^{p1}, \dots, x_{m0}^{p1}, x_{m1}^{p1}, \dots, x_{mn-1}^{p1}.$$

4: INIT -- CHARACTER\*1 Input  
 On entry: if the trigonometric coefficients required to compute the transforms are to be calculated by the routine and stored in the array TRIG, then INIT must be set equal to 'I' (Initial call).

If INIT contains 'S' (Subsequent call), then the routine assumes that trigonometric coefficients for the specified value of n are supplied in the array TRIG, having been calculated in a previous call to one of C06FPF, C06FQF or

C06FRF.

If INIT contains 'R' (Restart), then the routine assumes that trigonometric coefficients for the particular value of N are supplied in the array TRIG, but does not check that C06FPF, C06FQF or C06FRF have previously been called. This option allows the TRIG array to be stored in an external file, read in and re-used without the need for a call with INIT equal to 'I'. The routine carries out a simple test to check that the current value of n is compatible with the array TRIG. Constraint: INIT = 'I', 'S' or 'R'.

5: TRIG(2\*N) -- DOUBLE PRECISION array                   Input/Output  
On entry: if INIT = 'S' or 'R', TRIG must contain the required coefficients calculated in a previous call of the routine. Otherwise TRIG need not be set. On exit: TRIG contains the required coefficients (computed by the routine if INIT = 'I').

6: WORK(M\*N) -- DOUBLE PRECISION array                   Workspace

7: IFAIL -- INTEGER                                           Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1  
On entry M < 1.

IFAIL= 2  
On entry N < 1.

IFAIL= 3  
On entry INIT is not one of 'I', 'S' or 'R'.

IFAIL= 4  
On entry INIT = 'S', but none of C06FPF, C06FQF and C06FRF has previously been called.

IFAIL= 5

On entry INIT = 'S' or 'R', but the array TRIG and the current value of n are inconsistent.

7. Accuracy

Some indication of accuracy can be obtained by performing a subsequent inverse transform and comparing the results with the original sequence (in exact arithmetic they would be identical).

8. Further Comments

The time taken by the routine is approximately proportional to  $nm \cdot \log n$ , but also depends on the factors of n. The routine is fastest if the only prime factors of n are 2, 3 and 5, and is particularly slow if n is a large prime, or has large prime factors.

9. Example

This program reads in sequences of real data values which are assumed to be Hermitian sequences of complex data stored in Hermitian form. The sequences are expanded into full complex form using C06GSF and printed. The discrete Fourier transforms are then computed (using C06FQF) and printed out. Inverse transforms are then calculated by calling C06FPF followed by C06GQF showing that the original sequences are restored.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

C06FRF(3NAG)      Foundation Library (12/10/92)      C06FRF(3NAG)

C06 -- Summation of Series      C06FRF  
 C06FRF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

C06FRF computes the discrete Fourier transforms of m sequences, each containing n complex data values. This routine is designed to be particularly efficient on vector processors.

2. Specification

```

SUBROUTINE C06FRF (M, N, X, Y, INIT, TRIG, WORK, IFAIL)
INTEGER          M, N, IFAIL
DOUBLE PRECISION X(M*N), Y(M*N), TRIG(2*N), WORK(2*M*N)
CHARACTER*1     INIT

```

### 3. Description

Given  $m$  sequences of  $n$  complex data values  $z_j^p$ , for  $j=0,1,\dots,n-1$ ;  $p=1,2,\dots,m$ , this routine simultaneously calculates the Fourier transforms of all the sequences defined by:

$$z_k^p = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} z_j^p \exp(-i \frac{2(\pi)jk}{n}), \quad k=0,1,\dots,n-1; \quad p=1,2,\dots,m.$$

(Note the scale factor  $\frac{1}{\sqrt{n}}$  in this definition.)

$\sqrt{n}$

The discrete Fourier transform is sometimes defined using a positive sign in the exponential term

$$z_k^p = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} z_j^p \exp(+i \frac{2(\pi)jk}{n}).$$

To compute this form, this routine should be preceded and followed by a call of C06GCF to form the complex conjugates of

$z_j^p$  and the  $z_k^{\hat{p}}$ .

The routine uses a variant of the fast Fourier transform (FFT) algorithm (Brigham [1]) known as the Stockham self-sorting algorithm, which is described in Temperton [2]. Special code is provided for the factors 2, 3, 4, 5 and 6. This routine is designed to be particularly efficient on vector processors, and it becomes especially fast as  $m$ , the number of transforms to be computed in parallel, increases.

5. Parameters

- 1: M -- INTEGER Input  
 On entry: the number of sequences to be transformed, m.  
 Constraint: M >= 1.
  
- 2: N -- INTEGER Input  
 On entry: the number of complex values in each sequence, n.  
 Constraint: N >= 1.
  
- 3: X(M,N) -- DOUBLE PRECISION array Input/Output
  
- 4: Y(M,N) -- DOUBLE PRECISION array Input/Output  
 On entry: the real and imaginary parts of the complex data must be stored in X and Y respectively as if in a two-dimensional array of dimension (1:M,0:N-1); each of the m sequences is stored in a row of each array. In other words, if the real parts of the pth sequence to be transformed are denoted by  $x_j^p$ , for  $j=0,1,\dots,n-1$ , then the mn elements of the array X must contain the values
 

|  |   |    |      |   |     |    |      |   |      |     |      |   |     |      |   |     |      |   |
|--|---|----|------|---|-----|----|------|---|------|-----|------|---|-----|------|---|-----|------|---|
|  | 1 | 2  |      |   | m   | 1  | 2    |   |      | m   |      |   | 1   | 2    |   |     | m    |   |
|  | x | ,x | ,... | x | , x | ,x | ,... | x | ,... | x   | ,... | x | ,x  | ,... | x | ,x  | ,... | x |
|  | 0 | 0  |      | 0 | 1   | 1  |      | 1 |      | n-1 | n-1  |   | n-1 | n-1  |   | n-1 | n-1  |   |

 On exit: X and Y are overwritten by the real and imaginary parts of the complex transforms.
  
- 5: INIT -- CHARACTER\*1 Input  
 On entry: if the trigonometric coefficients required to compute the transforms are to be calculated by the routine and stored in the array TRIG, then INIT must be set equal to 'I' (Initial call).

If INIT contains 'S' (Subsequent call), then the routine assumes that trigonometric coefficients for the specified value of n are supplied in the array TRIG, having been calculated in a previous call to one of C06FPF, C06FQF or C06FRF.

If INIT contains 'R' (Restart) then the routine assumes that trigonometric coefficients for the particular value of n are supplied in the array TRIG, but does not check that C06FPF,

3. Description

This routine computes the two-dimensional discrete Fourier transform of a bivariate sequence of complex data values  $z_{j_1 j_2}$ ,

where  $j_1 = 0, 1, \dots, m-1$ ,  $j_2 = 0, 1, \dots, n-1$ .

The discrete Fourier transform is here defined by:

$$z_{k_1 k_2} = \frac{1}{\sqrt{mn}} \sum_{j_1=0}^{m-1} \sum_{j_2=0}^{n-1} z_{j_1 j_2} \exp(-2(\pi)i(\frac{j_1 k_1}{m} + \frac{j_2 k_2}{n})),$$

where  $k_1 = 0, 1, \dots, m-1$ ,  $k_2 = 0, 1, \dots, n-1$ .

(Note the scale factor of  $\frac{1}{\sqrt{mn}}$  in this definition.)

$$\sqrt{mn}$$

To compute the inverse discrete Fourier transform, defined with  $\exp(+2(\pi)i(\dots))$  in the above formula instead of  $\exp(-2(\pi)i(\dots))$ , this routine should be preceded and followed by calls of C06GCF to form the complex conjugates of the data values and the transform.

This routine calls C06FRF to perform multiple one-dimensional discrete Fourier transforms by the fast Fourier transform (FFT) algorithm in Brigham [1]. It is designed to be particularly efficient on vector processors.

4. References

 [2] Temperton C (1983) Self-sorting Mixed-radix Fast Fourier Transforms. J. Comput. Phys. 52 1--23.

5. Parameters

1: M -- INTEGER Input

On entry: the number of rows,  $m$ , of the arrays  $X$  and  $Y$ .  
 Constraint:  $M \geq 1$ .

2:  $N$  -- INTEGER Input  
 On entry: the number of columns,  $n$ , of the arrays  $X$  and  $Y$ .  
 Constraint:  $N \geq 1$ .

3:  $X(M,N)$  -- DOUBLE PRECISION array Input/Output

4:  $Y(M,N)$  -- DOUBLE PRECISION array Input/Output  
 On entry: the real and imaginary parts of the complex data values must be stored in arrays  $X$  and  $Y$  respectively. If  $X$  and  $Y$  are regarded as two-dimensional arrays of dimension  $(0:M-1,0:N-1)$ , then  $X(j_1, j_2)$  and  $Y(j_1, j_2)$  must contain the real and imaginary parts of  $z_{j_1 j_2}$ . On exit: the real and imaginary parts respectively of the corresponding elements of the computed transform.

5: INIT -- CHARACTER\*1 Input  
 On entry: if the trigonometric coefficients required to compute the transforms are to be calculated by the routine and stored in the arrays TRIGM and TRIGN, then INIT must be set equal to 'I', (Initial call).

If INIT contains 'S', (Subsequent call), then the routine assumes that trigonometric coefficients for the specified values of  $m$  and  $n$  are supplied in the arrays TRIGM and TRIGN, having been calculated in a previous call to the routine.

If INIT contains 'R', (Restart), then the routine assumes that trigonometric coefficients for the particular values of  $m$  and  $n$  are supplied in the arrays TRIGM and TRIGN, but does not check that the routine has previously been called. This option allows the TRIGM and TRIGN arrays to be stored in an external file, read in and re-used without the need for a call with INIT equal to 'I'. The routine carries out a simple test to check that the current values of  $m$  and  $n$  are compatible with the arrays TRIGM and TRIGN. Constraint: INIT = 'I', 'S' or 'R'.

6: TRIGM(2\*M) -- DOUBLE PRECISION array Input/Output

7: TRIGN(2\*N) -- DOUBLE PRECISION array Input/Output  
 On entry: if INIT = 'S' or 'R', TRIGM and TRIGN must contain the required coefficients calculated in a previous call of the routine. Otherwise TRIGM and TRIGN need not be set.

If  $m=n$  the same array may be supplied for TRIGM and TRIGN.  
 On exit: TRIGM and TRIGN contain the required coefficients  
 (computed by the routine if INIT = 'I').

8: WORK(2\*M\*N) -- DOUBLE PRECISION array                      Workspace

9: IFAIL -- INTEGER                                              Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not  
 familiar with this parameter (described in the Essential  
 Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see  
 Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are  
 output on the current error message unit (as defined by X04AAF).

IFAIL= 1  
 On entry  $M < 1$ .

IFAIL= 2  
 On entry  $N < 1$ .

IFAIL= 3  
 On entry INIT is not one of 'I', 'S' or 'R'.

IFAIL= 4  
 On entry INIT = 'S', but C06FUF has not previously been  
 called.

IFAIL= 5  
 On entry INIT = 'S' or 'R', but at least one of the arrays  
 TRIGM and TRIGN is inconsistent with the current value of M  
 or N.

## 7. Accuracy

Some indication of accuracy can be obtained by performing a  
 subsequent inverse transform and comparing the results with the  
 original sequence (in exact arithmetic they would be identical).

## 8. Further Comments

The time taken by the routine is approximately proportional to  
 $mn \cdot \log(mn)$ , but also depends on the factorization of the

1: X(N) -- DOUBLE PRECISION array Input/Output  
 On entry: if the data values  $z_j$  are written as  $x_j + iy_j$  and  
 if X is declared with bounds (0:N-1) in the (sub)program  
 from which C06GBF is called, then for  $0 \leq j \leq n/2$ , X(j) must  
 contain  $x_j (=x_j)$ , while for  $n/2 < j \leq n-1$ , X(j) must contain  
 $-y_{n-j} (=y_{n-j})$ . In other words, X must contain the Hermitian  
 sequence in Hermitian form. (See also Section 2.1.2 of the  
 Chapter Introduction). On exit: the imaginary parts  $y_j$  are  
 negated. The real parts  $x_j$  are not referenced.

2: N -- INTEGER Input  
 On entry: the number of data values, n. Constraint:  $N \geq 1$ .

3: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not  
 familiar with this parameter (described in the Essential  
 Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see  
 Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 $N < 1$ .

## 7. Accuracy

Exact.

## 8. Further Comments

The time taken by the routine is negligible.

## 9. Example

This program reads in a sequence of real data values, calls  
 C06EAF followed by C06GBF to compute their inverse discrete  
 Fourier transform, and prints this after expanding it from  
 Hermitian form into a full complex sequence.

The example program is not reproduced here. The source code for  
 all example programs is distributed with the NAG Foundation

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
N < 1.

## 7. Accuracy

Exact.

## 8. Further Comments

The time taken by the routine is negligible.

## 9. Example

This program reads in a sequence of complex data values and prints their inverse discrete Fourier transform as computed by calling C06GCF, followed by C06ECF and C06GCF again.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

C06 -- Summation of Series      C06GQF  
C06GQF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

C06GQF forms the complex conjugates of m Hermitian sequences, each containing n data values.

## 2. Specification

SUBROUTINE C06GQF (M, N, X, IFAIL)  
INTEGER            M, N, IFAIL

DOUBLE PRECISION X(M\*N)

3. Description

This is a utility routine for use in conjunction with C06FPF and C06FQF to calculate inverse discrete Fourier transforms (see the Chapter Introduction).

4. References

None.

5. Parameters

- 1: M -- INTEGER Input  
 On entry: the number of Hermitian sequences to be conjugated, m. Constraint: M >= 1.
  
- 2: N -- INTEGER Input  
 On entry: the number of data values in each Hermitian sequence, n. Constraint: N >= 1.
  
- 3: X(M,N) -- DOUBLE PRECISION array Input/Output  
 On entry: the data must be stored in array X as if in a two-dimensional array of dimension (1:M,0:N-1); each of the m sequences is stored in a row of the array in Hermitian form. If the n data values  $z_j$  are written as  $x_j + iy_j$ , then for  $0 <= j <= n/2$ ,  $x_j$  is contained in X(p,j), and for  $1 <= j <= (n-1)/2$ ,  $y_j$  is contained in X(p,n-j). (See also Section 2.1.2 of the Chapter Introduction.) On exit: the imaginary parts  $y_j$  are negated. The real parts  $x_j$  are not referenced.
  
- 4: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

$j$   
 contain the values  

$$\begin{array}{cccccccc} 1 & 2 & & m & 1 & 2 & & m & & 1 & 2 & & m \\ x, x, \dots, x, & x, x, \dots, x, \dots, & x, & x, & \dots, & x, \dots, & x, & x, & \dots, & x, & x, & \dots, & x \\ 0 & 0 & & 0 & 1 & 1 & & 1 & & n-1 & n-1 & & n-1 \end{array}$$

6: IFAIL -- INTEGER Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry  $M < 1$ .

IFAIL= 2

On entry  $N < 1$ .

#### 7. Accuracy

Exact.

#### 8. Further Comments

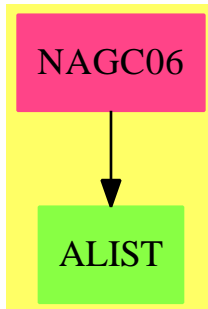

None.

#### 9. Example

This program reads in sequences of real data values which are assumed to be Hermitian sequences of complex data stored in Hermitian form. The sequences are then expanded into full complex form using C06GSF and printed.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

This package uses the NAG Library to compute some commonly occurring physical and mathematical functions.

S -- Approximations of Special Functions      Introduction -- S  
Chapter S  
Approximations of Special Functions

### 1. Scope of the Chapter

This chapter is concerned with the provision of some commonly occurring physical and mathematical functions.

### 2. Background to the Problems

The majority of the routines in this chapter approximate real-valued functions of a single real argument, and the techniques involved are described in Section 2.1. In addition the chapter contains routines for elliptic integrals (see Section 2.2), Bessel and Airy functions of a complex argument (see Section 2.3), and exponential of a complex argument.

#### 2.1. Functions of a Single Real Argument

Most of the routines for functions of a single real argument have been based on truncated Chebyshev expansions. This method of approximation was adopted as a compromise between the conflicting requirements of efficiency and ease of implementation on many different machine ranges. For details of the reasons behind this choice and the production and testing procedures followed in

constructing this chapter see Schonfelder [7].

Basically if the function to be approximated is  $f(x)$ , then for  $x$  in  $[a,b]$  an approximation of the form

$$f(x) \approx g(x) + \sum_{r=0}^n C_r T_r(t)$$

is used, (  $\sum$  denotes, according to the usual convention, a

summation in which the first term is halved), where  $g(x)$  is some suitable auxiliary function which extracts any singularities, asymptotes and, if possible, zeros of the function in the range in question and  $t=t(x)$  is a mapping of the general range  $[a,b]$  to the specific range  $[-1,+1]$  required by the Chebyshev polynomials,  $T_r(t)$ . For a detailed description of the properties of the Chebyshev polynomials see Clenshaw [5] and Fox and Parker [6].

The essential property of these polynomials for the purposes of function approximation is that  $T_n(t)$  oscillates between  $+1$  and  $-1$  it takes its extreme values  $n+1$  times in the interval  $[-1,+1]$ . Therefore, provided the coefficients  $C_r$  decrease in magnitude sufficiently rapidly the error made by truncating the Chebyshev expansion after  $n$  terms is approximately given by

$$E(t) \approx C_{n+1} T_{n+1}(t)$$

That is the error oscillates between  $\pm C_{n+1}$  and takes its extreme value  $n+1$  times in the interval in question. Now this is just the condition that the approximation be a mini-max representation, one which minimizes the maximum error. By suitable choice of the interval,  $[a,b]$ , the auxiliary function,  $g(x)$ , and the mapping of the independent variable,  $t(x)$ , it is almost always possible to obtain a Chebyshev expansion with rapid convergence and hence truncations that provide near mini-max polynomial approximations to the required function. The difference between the true mini-max polynomial and the truncated Chebyshev expansion is seldom sufficiently great to be of significance.

The evaluation of the Chebyshev expansions follows one of two

methods. The first and most efficient, and hence most commonly used, works with the equivalent simple polynomial. The second method, which is used on the few occasions when the first method proves to be unstable, is based directly on the truncated Chebyshev series and uses backward recursion to evaluate the sum. For the first method, a suitably truncated Chebyshev expansion (truncation is chosen so that the error is less than the machine precision) is converted to the equivalent simple polynomial. That is we evaluate the set of coefficients  $b_r$  such that

$$y(t) = \sum_{r=0}^{n-1} b_r t^r = \sum_{r=0}^{n-1} C_r T_r(t).$$

The polynomial can then be evaluated by the efficient Horner's method of nested multiplications,

$$y(t) = (b_0 + t(b_1 + t(b_2 + \dots + t(b_{n-2} + tb_{n-1}))))).$$

This method of evaluation results in efficient routines but for some expansions there is considerable loss of accuracy due to cancellation effects. In these cases the second method is used. It is well known that if

$$\begin{aligned} b_{n-1} &= C \\ b_{n-2} &= 2tb_{n-1} + C \\ b_j &= 2tb_{j+1} - b_{j+2} + C, \quad j=n-3, n-4, \dots, 0 \end{aligned}$$

then

$$\sum_{r=0}^{n-1} C_r T_r(t) = -(b_{n-2} - b_{n-1})$$

and this is always stable. This method is most efficiently implemented by using three variables cyclically and explicitly constructing the recursion.

That is,

$$\begin{aligned}
 (\alpha) &= C \\
 (\beta) &= 2t(\alpha)+C \\
 (\gamma) &= 2t(\beta)-(\alpha)+C \\
 (\alpha) &= 2t(\gamma)-(\beta)+C \\
 (\beta) &= 2t(\alpha)-(\gamma)+C \\
 &\dots \\
 (\alpha) &= 2t(\gamma)-(\beta)+C \quad (\text{say}) \\
 (\beta) &= 2t(\alpha)-(\gamma)+C \\
 y(t) &= t(\beta)-(\alpha)+ \dots
 \end{aligned}$$

The auxiliary functions used are normally functions compounded of simple polynomial (usually linear) factors extracting zeros, and the primary compiler-provided functions, sin, cos, ln, exp, sqrt, which extract singularities and/or asymptotes or in some cases basic oscillatory behaviour, leaving a smooth well-behaved function to be approximated by the Chebyshev expansion which can therefore be rapidly convergent.

The mappings of [a,b] to [-1,+1] used, range from simple linear mappings to the case when b is infinite and considerable improvement in convergence can be obtained by use of a bilinear form of mapping. Another common form of mapping is used when the function is even, that is it involves only even powers in its expansion. In this case an approximation over the whole interval

[-a,a] can be provided using a mapping  $t=2(-) -1$ . This embodies the evenness property but the expansion in t involves all powers and hence removes the necessity of working with an expansion with half its coefficients zero.

For many of the routines an analysis of the error in principle is given, viz, if E and (nabla) are the absolute errors in function and argument and (epsilon) and (delta) are the corresponding relative errors, then

$$E \sim |f'(x)|(\text{nabla})$$

$$E \sim |xf'(x)|(\text{delta})$$

$$(\text{epsilon})^{\sim} = \frac{|xf'(x)|}{|f(x)|} (\text{delta})$$

If we ignore errors that arise in the argument of the function by propagation of data errors etc and consider only those errors that result from the fact that a real number is being represented in the computer in floating-point form with finite precision, then  $(\text{delta})$  is bounded and this bound is independent of the magnitude of  $x$ ; e.g. on an 11-digit machine

$$|(\text{delta})| \leq 10^{-11}.$$

(This of course implies that the absolute error  $(\text{nabla}) = x(\text{delta})$  is also bounded but the bound is now dependent on  $x$ ). However because of this the last two relations above are probably of more interest. If possible the relative error propagation is discussed; that is the behaviour of the error amplification factor  $|xf'(x)/f(x)|$  is described, but in some cases, such as near zeros of the function which cannot be extracted explicitly, absolute error in the result is the quantity of significance and here the factor  $|xf'(x)|$  is described. In general, testing of the functions has shown that their error behaviour follows fairly well these theoretical error behaviours. In regions, where the error amplification factors are less than or of the order of one, the errors are slightly larger than the above predictions. The errors are here limited largely by the finite precision of arithmetic in the machine but  $(\text{epsilon})$  is normally no more than a few times greater than the bound on  $(\text{delta})$ . In regions where the amplification factors are large, order of ten or greater, the theoretical analysis gives a good measure of the accuracy obtainable.

It should be noted that the definitions and notations used for the functions in this chapter are all taken from Abramowitz and Stegun [1]. Users are strongly recommended to consult this book for details before using the routines in this chapter.

## 2.2. Approximations to Elliptic Integrals

The functions provided here are symmetrised variants of the classic elliptic integrals. These alternative definitions have been suggested by Carlson (see [2], [3] and [4]) and he also developed the basic algorithms used in this chapter.

The standard integral of the first kind is represented by

infty

$$R(x,y,z) = \int_0^1 \frac{dt}{\sqrt{(t+x)(t+y)(t+z)}}$$

where  $x,y,z \geq 0$  and at most one may be equal to zero.

The normalisation factor,  $\frac{1}{2}$ , is chosen so as to make

$$R(x,x,x) = \frac{1}{\sqrt{x}}$$

If any two of the variables are equal,  $R$  degenerates into the second function

$$R(x,y) = \int_0^{\infty} \frac{dt}{\sqrt{t+x(t+y)}}$$

where the argument restrictions are now  $x \geq 0$  and  $y \neq 0$ .

This function is related to the logarithm or inverse hyperbolic functions if  $0 < y < x$ , and to the inverse circular functions if  $0 < x < y$ .

The integrals of the second kind are defined by

$$R(x,y,z) = \int_0^{\infty} \frac{dt}{\sqrt{(t+x)(t+y)(t+z)^3}}$$

with  $z > 0$ ,  $x \geq 0$  and  $y \geq 0$  but only one of  $x$  or  $y$  may be zero.

The function is a degenerate special case of the integral of the third kind

$$R(x,y,z,(\rho)) = \int_0^{\infty} \frac{dt}{\sqrt{(t+x)(t+y)(t+z)^3}}$$

$$J = \frac{2}{0} \left( \frac{1}{\sqrt{(t+x)(t+y)(t+z)}(t+\rho)} \right)$$

with  $\rho \neq 0, x, y, z \geq 0$  with at most one equality holding. Thus  $R(x, y, z) = R(x, y, z, z)$ . The normalisation of both these functions  $D$   $J$  is chosen so that

$$R(x, x, x) = R(x, x, x, x) = 1/(x \sqrt{x})$$

The algorithms used for all these functions are based on duplication theorems. These allow a recursion system to be established which constructs a new set of arguments from the old using a combination of arithmetic and geometric means. The value of the function at the original arguments can then be simply related to the value at the new arguments. These recursive reductions are used until the arguments differ from the mean by an amount small enough for a Taylor series about the mean to give sufficient accuracy when retaining terms of order less than six. Each step of the recurrences reduces the difference from the mean by a factor of four, and as the truncation error is of order six, the truncation error goes like  $(4/9)^n$ , where  $n$  is the number of iterations.

The above forms can be related to the more traditional canonical forms (see Abramowitz and Stegun [1], 17.2).

If we write  $q = \cos(\phi), r = 1 - m \cdot \sin(\phi), s = 1 + n \cdot \sin(\phi)$ , where  $0 < \phi \leq \pi/2$ , we have: the elliptic integral of the first kind:

$$F(\phi|m) = \int_0^{\phi} \frac{\sin(t)}{\sqrt{(1-t^2)(1-mt^2)}} dt = \sin(\phi) \cdot R(q, r, 1);$$

the elliptic integral of the second kind:

$$E(\phi|m) = \int_0^{\phi} \frac{\sin(t) \sqrt{1-mt^2}}{\sqrt{(1-t^2)(1-mt^2)}} dt$$

$$= \frac{\sin(\phi).R(q,r,1) - m \sin^3(\phi).R(q,r,1)}{F \quad 3 \quad D}$$

the elliptic integral of the third kind:

$$(\text{Pi})(n;(\phi)|m) = \frac{\int_0^{\sin(\phi)} \frac{dt}{(1-t^2)^{-1/2} (1-mt^2)^{-1/2} (1+nt^2)^{-1}}$$

$$= \frac{\sin(\phi).R(q,r,1) - n \sin^3(\phi).R(q,r,1,s)}{F \quad 3 \quad J}$$

Also the complete elliptic integral of the first kind:

$$K(m) = \frac{\int_0^{(\pi)/2} \frac{d(\theta)}{(1-m \sin^2(\theta))^{-1/2}} = R(0,1-m,1);$$

the complete elliptic integral of the second kind:

$$E(m) = \frac{\int_0^{(\pi)/2} (1-m \sin^2(\theta))^{1/2} d(\theta) = R(0,1-m,1) - mR(0,1-m,1).$$

### 2.3. Bessel and Airy Functions of a Complex Argument

The routines for Bessel and Airy functions of a real argument are based on Chebyshev expansions, as described in Section 2.1. The routines for functions of a complex argument, however, use different methods. These routines relate all functions to the modified Bessel functions  $I_{(\nu)}(z)$  and  $K_{(\nu)}(z)$  computed in the right-half complex plane, including their analytic continuations.  $I_{(\nu)}$  and  $K_{(\nu)}$  are computed by different methods according to the values of  $\text{zand}(\nu)$ . The methods include power series, asymptotic expansions and Wronskian evaluations. The relations between functions are based on well known formulae (see Abramowitz and Stegun [1]).

## 3. Recommendations on Choice and Use of Routines

## 3.1. Elliptic Integrals

IMPORTANT ADVICE: users who encounter elliptic integrals in the course of their work are strongly recommended to look at transforming their analysis directly to one of the Carlson forms, rather than the traditional canonical Legendre forms. In general, the extra symmetry of the Carlson forms is likely to simplify the analysis, and these symmetric forms are much more stable to calculate.

The routine S21BAF for R is largely included as an auxiliary to  $C$  the other routines for elliptic integrals. This integral essentially calculates elementary functions, e.g.

$$\ln x = (x-1) \cdot R \left( \frac{(1+x)^2}{4}, x \right), x > 0;$$

$$\arcsin x = x \cdot R \left( 1-x^2, 1 \right), |x| \leq 1;$$

$C$

$$\operatorname{arcsinh} x = x.R(1+x, 1), \text{ etc}$$

C

In general this method of calculating these elementary functions is not recommended as there are usually much more efficient specific routines available in the Library. However, S21BAF may be used, for example, to compute  $\ln x/(x-1)$  when  $x$  is close to 1, without the loss of significant figures that occurs when  $\ln x$  and  $x-1$  are computed separately.

### 3.2. Bessel and Airy Functions

For computing the Bessel functions  $J_{(\nu)}(x)$ ,  $Y_{(\nu)}(x)$ ,  $I_{(\nu)}(x)$  and  $K_{(\nu)}(x)$  where  $x$  is real and  $(\nu)=0$  or 1, special routines are provided, which are much faster than the more general routines that allow a complex argument and arbitrary real  $(\nu) \geq 0$  functions and their derivatives  $Ai(x)$ ,  $Bi(x)$ ,  $Ai'(x)$ ,  $Bi'(x)$  for a real argument which are much faster than the routines for complex arguments.

S01 -- Approximations of Special Functions S01EAF  
 S01EAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S01EAF evaluates the exponential function  $e^z$ , for complex z.

2. Specification

```

COMPLEX(KIND(1.0D0)) FUNCTION S01EAF (Z, IFAIL)
INTEGER IFAIL
COMPLEX(KIND(1.0D0)) Z
    
```

3. Description

This routine evaluates the exponential function  $e^z$ , taking care to avoid machine overflow, and giving a warning if the result cannot be computed to more than half precision. The function is evaluated as  $e^z = e^{x+iy} = e^x (\cos y + i \sin y)$ , where x and y are the real and imaginary parts respectively of z.

Since  $\cos y$  and  $\sin y$  are less than or equal to 1 in magnitude, it is possible that  $e^x$  may overflow although  $e^{\cos y}$  or  $e^{\sin y}$  does not. In this case the alternative formula  $\text{sign}(\cos y)e^{x+\ln|\cos y|}$  is used for the real part of the result, and  $\text{sign}(\sin y)e^{x+\ln|\sin y|}$  for the imaginary part. If either part of the result still overflows, a warning is returned through parameter IFAIL.

If  $\text{Im } z$  is too large, precision may be lost in the evaluation of  $\sin y$  and  $\cos y$ . Again, a warning is returned through IFAIL.

4. References

None.

## 5. Parameters

- 1: Z -- COMPLEX(KIND(1.0D0)) Input  
 On entry: the argument z of the function.
- 2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

The real part of the result overflows, and is set to the largest safe number with the correct sign. The imaginary part of the result is meaningful.

IFAIL= 2

The imaginary part of the result overflows, and is set to the largest safe number with the correct sign. The real part of the result is meaningful.

IFAIL= 3

Both real and imaginary parts of the result overflow, and are set to the largest safe number with the correct signs.

IFAIL= 4

The computed result is accurate to less than half precision, due to the size of  $\text{Im } z$ .

IFAIL= 5

The computed result has no precision, due to the size of  $\text{Im } z$ , and is set to zero.

## 7. Accuracy

Accuracy is limited in general only by the accuracy of the Fortran intrinsic functions in the computation of  $\text{siny}$ ,  $\text{cosy}$  and  $e^x$ , where  $x = \text{Re } z$ ,  $y = \text{Im } z$ . As  $y$  gets larger, precision will probably be lost due to argument reduction in the evaluation of the sine and cosine functions, until the warning error IFAIL = 4

occurs when  $y$  gets larger than  $\sqrt{1/(\text{epsilon})}$ , where  $(\text{epsilon})$  is the machine precision. Note that on some machines, the intrinsic functions SIN and COS will not operate on arguments larger than

about  $\sqrt{1/(\text{epsilon})}$ , and so IFAIL can never return as 4.

In the comparatively rare event that the result is computed by the formulae  $\text{sign}(\text{cosy})e^{x+\ln|\text{cosy}|}$  and  $\text{sign}(\text{siny})e^{x+\ln|\text{siny}|}$ , a further small loss of accuracy may be expected due to rounding errors in the logarithmic function.

8. Further Comments

None.

9. Example

The example program reads values of the argument  $z$  from a file, evaluates the function at each value of  $z$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S13 -- Approximations of Special Functions S13AAF  
 S13AAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S13AAF returns the value of the exponential integral  $E(x)$ , via the routine name.

2. Specification

```
DOUBLE PRECISION FUNCTION S13AAF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

3. Description

The routine calculates an approximate value for

$$E(x) = \int_0^{\infty} \frac{e^{-u}}{u} du, \quad x > 0.$$

For  $0 < x \leq 4$ , the approximation is based on the Chebyshev expansion

$$E(x) = y(t) - \ln x = \sum_{r=0}^{\infty} a_r T_r(t) - \ln x, \quad \text{where } t = \frac{1}{-x-1}.$$

For  $x > 4$ ,

$$E(x) = \frac{e^{-x}}{x} y(t) = \frac{e^{-x}}{x} \sum_{r=0}^{\infty} a_r T_r(t),$$

$$\text{where } t = -1.0 + 14.5/(x+3.25) = \frac{11.25-x}{3.25+x}.$$

In both cases,  $-1 \leq t \leq +1$ .

To guard against producing underflows, if  $x > x_{hi}$  the result is set directly to zero. For the value  $x_{hi}$  see the Users' Note for your implementation.

#### 4. References

- [1] Abramowitz M and Stegun I A (1965) Handbook of Mathematical Functions. Dover Publications. Ch. 26.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
 On entry: the argument x of the function. Constraint: X > 0.  
 0.
- 2: IFAIL -- INTEGER Input/Output  
 Before entry, IFAIL must be assigned a value. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

Unless the routine detects an error (see Section 6), IFAIL contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

The routine has been called with an argument less than or equal to zero for which the function is not defined. The result returned is zero.

7. Accuracy

If (delta) and (epsilon) are the relative errors in argument and result respectively, then in principle,

$$|(\text{epsilon})|^{\sim} = \frac{e^{-x}}{E(x)} * (\text{delta})$$

so the relative error in the argument is amplified in the result by at least a factor  $e^{-x}$ .

The equality should hold if (delta) is greater than the machine precision ((delta) due to data errors etc) but if (delta) is simply a result of round-off in the machine representation, it is possible that an extra figure may be lost in internal calculation and round-off.

The behaviour of this amplification factor is shown in Figure 1.

Figure 1  
Please see figure in printed Reference Manual

It should be noted that, for small x, the amplification factor tends to zero and eventually the error in the result will be limited by machine precision.

For large x,

$$(\text{epsilon})^{\sim} x(\text{delta}) = (\text{Delta}),$$

the absolute error in the argument.

8. Further Comments

None.

### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

      S13ACF -- NAG Foundation Library Routine Document
```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S13ACF returns the value of the cosine integral

$$Ci(x) = (\gamma) + \ln x + \int_0^x \frac{\cos u - 1}{u} du, \quad x > 0$$

via the routine name, where  $(\gamma)$  denotes Euler's constant.

#### 2. Specification

```
DOUBLE PRECISION FUNCTION S13ACF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

#### 3. Description

The routine calculates an approximate value for  $Ci(x)$ .

For  $0 < x \leq 16$  it is based on the Chebyshev expansion

$$Ci(x) = \ln x + \sum_{r=0}^{16} a_r T_r\left(\frac{x}{16}\right) - 1.$$

For  $16 < x < x_{hi}$  where the value of  $x_{hi}$  is given in the Users' Note for your implementation,

$$Ci(x) = \frac{f(x)\sin x}{x} - \frac{g(x)\cos x}{x^2}$$

where  $f(x) = \int_0^x T(t) dt$  and  $g(x) = \int_0^x g T(t) dt$ ,  $t = 2(x - 1)$ .

For  $x \geq x_{hi}$ ,  $Ci(x) = 0$  to within the accuracy possible (see Section 7).

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

- 1: X -- DOUBLE PRECISION Input  
On entry: the argument x of the function. Constraint: X > 0.0.
- 2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
The routine has been called with an argument less than or equal to zero for which the function is not defined. The result returned is zero.

7. Accuracy

If E and (epsilon) are the absolute and relative errors in the

result and  $(\delta)$  is the relative error in the argument then in principle these are related by

$$|E| \sim |(\delta)\cos x| \text{ and } |(\epsilon)| \sim \frac{|(\delta)\cos x|}{|Ci(x)|}$$

That is accuracy will be limited by machine precision near the origin and near the zeros of  $\cos x$ , but near the zeros of  $Ci(x)$  only absolute accuracy can be maintained.

The behaviour of this amplification is shown in Figure 1.

Figure 1  
Please see figure in printed Reference Manual

For large values of  $x$ ,  $Ci(x) \sim \frac{\sin x}{x}$  therefore  $(\epsilon) \sim (\delta)x \cot x$  and since  $(\delta)$  is limited by the finite precision of the machine it becomes impossible to return results which have any relative accuracy. That is, when  $x > 1/(\delta)$  we have that  $|Ci(x)| < 1/x \sim E$  and hence is not significantly different from zero.

Hence  $x_{hi}$  is chosen such that for values of  $x > x_{hi}$ ,  $Ci(x)$  in principle would have values less than the machine precision and so is essentially zero.

8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S13ADF returns the value of the sine integral

$$Si(x) = \int_0^x \frac{\sin u}{u} du,$$

via the routine name.

2. Specification

```
DOUBLE PRECISION FUNCTION S13ADF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

3. Description

The routine calculates an approximate value for Si(x).

For |x| ≤ 16.0 it is based on the Chebyshev expansion

$$Si(x) = x - \sum_{r=0}^{\infty} a_r T_r(t), \quad t = 2 \left( \frac{x}{16} \right)^2 - 1.$$

For 16 < |x| < x<sub>hi</sub>, where x<sub>hi</sub> is an implementation dependent number,

$$Si(x) = \text{sign}(x) \left\{ \frac{(\pi) f(x) \cos x}{x^2} - \frac{g(x) \sin x}{x^2} \right\}$$

where  $f(x) = \sum_{r=0}^{\infty} f_r T_r(t)$  and  $g(x) = \sum_{r=0}^{\infty} g_r T_r(t)$ ,  $t = 2 \left( \frac{x}{16} \right)^2 - 1$ .

For |x| > x<sub>hi</sub>, Si(x) = -(\pi)signx to within machine precision.

## 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

## 5. Parameters

1: X -- DOUBLE PRECISION Input  
 On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL has been included for consistency with other routines in this chapter.

## 7. Accuracy

If (delta) and (epsilon) are the relative errors in the argument and result, respectively, then in principle

$$|(\text{epsilon})|^{\sim} = \frac{|\text{(delta)}\text{sin}x|}{|\text{Si}(x)|}$$

The equality may hold if (delta) is greater than the machine precision ((delta) due to data errors etc) but if (delta) is simply due to round-off in the machine representation, then since the factor relating (delta) to (epsilon) is always less than one, the accuracy will be limited by machine precision.

## 8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

## 9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S14 -- Approximations of Special Functions S14AAF  
 S14AAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S14AAF returns the value of the Gamma function (Gamma)(x), via the routine name.

2. Specification

```
DOUBLE PRECISION FUNCTION S14AAF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Gamma function (Gamma)(x). The routine is based on the Chebyshev expansion:

$$\begin{aligned} & \text{--'} \\ (\text{Gamma})(1+u) &= > a T(t), \text{ where } 0 \leq u < 1, t = 2u - 1, \\ & \text{-- } r r \\ & r = 0 \end{aligned}$$

and uses the property (Gamma)(1+x)=x(Gamma)(x). If x=N+1+u where N is integral and 0<=u<1 then it follows that:

$$\begin{aligned} \text{for } N > 0 \quad (\text{Gamma})(x) &= (x-1)(x-2) \dots (x-N) (\text{Gamma})(1+u), \\ \text{for } N = 0 \quad (\text{Gamma})(x) &= (\text{Gamma})(1+u), \\ \text{for } N < 0 \quad (\text{Gamma})(x) &= \frac{(\text{Gamma})(1+u)}{x(x+1)(x+2) \dots (x-N-1)}. \end{aligned}$$

There are four possible failures for this routine:

- (i) if x is too large, there is a danger of overflow since (Gamma)(x) could become too large to be represented in the

machine;

(ii) if  $x$  is too large and negative, there is a danger of underflow;

(iii) if  $x$  is equal to a negative integer,  $(\Gamma)(x)$  would overflow since it has poles at such points;

(iv) if  $x$  is too near zero, there is again the danger of overflow on some machines. For small  $x$ ,  $(\Gamma)(x) \sim \frac{1}{x}$ , and on some machines there exists a range of non-zero but small values of  $x$  for which  $1/x$  is larger than the greatest representable value.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

1: X -- DOUBLE PRECISION Input  
 On entry: the argument  $x$  of the function. Constraint:  $X$  must not be a negative integer.

2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 The argument is too large. On soft failure the routine returns the approximate value of  $(\Gamma)(x)$  at the nearest valid argument.

IFAIL= 2  
 The argument is too large and negative. On soft failure the routine returns zero.

IFAIL= 3  
 The argument is too close to zero. On soft failure the

routine returns the approximate value of  $(\Gamma)(x)$  at the nearest valid argument.

IFAIL= 4

The argument is a negative integer, at which value  $(\Gamma)(x)$  is infinite. On soft failure the routine returns a large positive value.

#### 7. Accuracy

Let  $(\delta)$  and  $(\epsilon)$  be the relative errors in the argument and the result respectively. If  $(\delta)$  is somewhat larger than the machine precision (i.e., is due to data errors etc), then  $(\epsilon)$  and  $(\delta)$  are approximately related by:

$$(\epsilon) \sim |x(\Psi)(x)|(\delta)$$

(provided  $(\epsilon)$  is also greater than the representation error). Here  $(\Psi)(x)$  is the digamma function  $\frac{(\Gamma)'(x)}{(\Gamma)(x)}$ .

Figure 1 shows the behaviour of the error amplification factor  $|x(\Psi)(x)|$ .

Figure 1

Please see figure in printed Reference Manual

If  $(\delta)$  is of the same order as machine precision, then rounding errors could make  $(\epsilon)$  slightly larger than the above relation predicts.

There is clearly a severe, but unavoidable, loss of accuracy for arguments close to the poles of  $(\Gamma)(x)$  at negative integers. However relative accuracy is preserved near the pole at  $x=0$  right up to the point of failure arising from the danger of overflow.

Also accuracy will necessarily be lost as  $x$  becomes large since in this region

$$(\epsilon) \sim (\delta)x \ln x.$$

However since  $(\Gamma)(x)$  increases rapidly with  $x$ , the routine must fail due to the danger of overflow before this loss of accuracy is too great. (e.g. for  $x=20$ , the amplification factor  $\sim 60$ .)

#### 8. Further Comments

For details of the time taken by the routine see the Users' Note

for your implementation.

### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

```

```
S14 -- Approximations of Special Functions          S14ABF
      S14ABF -- NAG Foundation Library Routine Document
```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S14ABF returns a value for the logarithm of the Gamma function,  $\ln(\Gamma(x))$ , via the routine name.

#### 2. Specification

```
DOUBLE PRECISION FUNCTION S14ABF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

#### 3. Description

This routine evaluates an approximation to  $\ln(\Gamma(x))$ . It is based on two Chebyshev expansions.

For  $0 < x \leq x_{\text{small}}$ ,  $\ln(\Gamma(x)) = -\ln x$  to within machine accuracy.

For  $x_{\text{small}} < x \leq 15.0$ , the recursive relation

$(\Gamma(1+x)) = x(\Gamma(x))$  is used to reduce the calculation to one involving  $(\Gamma(1+u))$ ,  $0 \leq u < 1$  which is evaluated as:

$$(\Gamma(1+u)) = \int_0^{\infty} t^u e^{-t} dt, \quad t=2u-1.$$

Once (Gamma)(x) has been calculated, the required result is produced by taking the logarithm.

For  $15.0 < x \leq x_{big}$ ,

$$\ln(\text{Gamma})(x) = (x - \frac{1}{2}) \ln x - x + \frac{1}{2} \ln 2(\pi) + y(x)/x$$

where  $y(x) = \sum_{r=0}^{\infty} \frac{b_r}{r!} T_r(t)$ ,  $t = 2(x - \frac{1}{2})^{-1}$ .

For  $x < x_{big}$  the term  $y(x)/x$  is negligible and so its calculation is omitted.

For  $x > x_{big}$  there is a danger of setting overflow so the routine must fail.

For  $x \leq 0.0$  the function is not defined and the routine fails.

Note:  $x_{small}$  is calculated so that if  $x < x_{small}$ , (Gamma)(x)=1/x to within machine accuracy.  $x_{big}$  is calculated so that if  $x > x_{big}$ ,

$$\ln(\text{Gamma})(x) = (x - \frac{1}{2}) \ln x - x + \frac{1}{2} \ln 2(\pi)$$

to within machine accuracy.  $x_{vbig}$  is calculated so that  $\ln(\text{Gamma})(x_{vbig})$  is close to the value returned by X02ALF(\*).

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

- 1: X -- DOUBLE PRECISION Input  
 On entry: the argument x of the function. Constraint: X > 0.  
 0.

2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 X <= 0.0, the function is undefined. On soft failure, the routine returns zero.

IFAIL= 2  
 X is too large, the function would overflow. On soft failure, the routine returns the value of the function at the largest permissible argument.

## 7. Accuracy

Let  $(\delta)$  and  $(\epsilon)$  be the relative errors in the argument and result respectively, and  $E$  be the absolute error in the result.

If  $(\delta)$  is somewhat larger than the relative machine precision, then

$$E \sim |x*(\Psi)(x)|(\delta) \text{ and } (\epsilon) \sim \frac{|x*(\Psi)(x)|}{|\ln(\Gamma)(x)|}(\delta)$$

where  $(\Psi)(x)$  is the digamma function  $\frac{(\Gamma)'(x)}{(\Gamma)(x)}$ . Figure 1 and Figure 2 show the behaviour of these error amplification factors.

Figure 1

Please see figure in printed Reference Manual

Figure 2

Please see figure in printed Reference Manual

These show that relative error can be controlled, since except near  $x=1$  or  $2$  relative error is attenuated by the function or at least is not greatly amplified.

( 1 )

For large x,  $(\epsilon) \sim (1 + \frac{1}{\ln x}) \delta$  and for small x,

( ln x )

1

$(\epsilon) \sim \frac{1}{\ln x} \delta$ .

The function  $\ln(\Gamma(x))$  has zeros at  $x=1$  and  $2$  and hence relative accuracy is not maintainable near those points. However absolute accuracy can still be provided near those zeros as is shown above.

If however,  $\delta$  is of the order of the machine precision, then rounding errors in the routine's internal arithmetic may result in errors which are slightly larger than those predicted by the equalities. It should be noted that even in areas where strong attenuation of errors is predicted the relative precision is bounded by the effective machine precision.

8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S14 -- Approximations of Special Functions S14BAF  
 S14BAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S14BAF computes values for the incomplete gamma functions  $P(a,x)$  and  $Q(a,x)$ .

2. Specification

```

SUBROUTINE S14BAF (A, X, TOL, P, Q, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION A, X, TOL, P, Q

```

### 3. Description

This subroutine evaluates the incomplete gamma functions in the normalised form

$$P(a,x) = \frac{1}{(\Gamma(a))} \int_0^x t^{a-1} e^{-t} dt,$$

$$Q(a,x) = \frac{1}{(\Gamma(a))} \int_x^{\infty} t^{a-1} e^{-t} dt,$$

with  $x \geq 0$  and  $a > 0$ , to a user-specified accuracy. With this normalisation,  $P(a,x) + Q(a,x) = 1$ .

Several methods are used to evaluate the functions depending on the arguments  $a$  and  $x$ , the methods including Taylor expansion for  $P(a,x)$ , Legendre's continued fraction for  $Q(a,x)$ , and power series for  $Q(a,x)$ . When both  $a$  and  $x$  are large, and  $a \sim x$ , the uniform asymptotic expansion of Temme [3] is employed for greater efficiency - specifically, this expansion is used when  $a \geq 20$  and  $0.7a \leq x \leq 1.4a$ .

Once either of  $P$  or  $Q$  is computed, the other is obtained by subtraction from 1. In order to avoid loss of relative precision in this subtraction, the smaller of  $P$  and  $Q$  is computed first.

This routine is derived from subroutine GAM in Gautschi [2].

### 4. References

- [2] Gautschi W (1979) Algorithm 542: Incomplete Gamma Functions. ACM Trans. Math. Softw. 5 482--489.
- [3] Temme N M (1987) On the Computation of the Incomplete Gamma Functions for Large Values of the Parameters. Algorithms for Approximation. (ed J C Mason and M G Cox) Oxford University Press.

## 5. Parameters

- 1: A -- DOUBLE PRECISION Input  
On entry: the argument a of the functions. Constraint: A > 0.0.
- 2: X -- DOUBLE PRECISION Input  
On entry: the argument x of the functions. Constraint: X >= 0.0.
- 3: TOL -- DOUBLE PRECISION Input  
On entry: the relative accuracy required by the user in the results. If S14BAF is entered with TOL greater than 1.0 or less than machine precision, then the value of machine precision is used instead.
- 4: P -- DOUBLE PRECISION Output
- 5: Q -- DOUBLE PRECISION Output  
On exit: the values of the functions P(a,x) and Q(a,x) respectively.
- 6: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

On entry A <= 0.0.

IFAIL= 2

On entry X < 0.0.

IFAIL= 3

Convergence of the Taylor series or Legendre continued fraction fails within 600 iterations. This error is extremely unlikely to occur; if it does, contact NAG.

## 7. Accuracy

There are rare occasions when the relative accuracy attained is somewhat less than that specified by parameter TOL. However, the

error should never exceed more than one or two decimal places. Note also that there is a limit of 18 decimal places on the achievable accuracy, because constants in the routine are given to this precision.

#### 8. Further Comments

The time taken for a call of S14BAF depends on the precision requested through TOL, and also varies slightly with the input arguments a and x.

#### 9. Example

The example program reads values of the argument a and x from a file, evaluates the function and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S15 -- Approximations of Special Functions S15ADF  
 S15ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S15ADF returns the value of the complementary error function,  $\operatorname{erfc}x$ , via the routine name.

#### 2. Specification

```
DOUBLE PRECISION FUNCTION S15ADF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

#### 3. Description

The routine calculates an approximate value for the complement of the error function

$$\operatorname{erfc} x = \frac{\int_x^{\infty} e^{-u^2} du}{\sqrt{\pi}}$$

$$\frac{1}{\sqrt{\pi} x}$$

For  $x \geq 0$ , it is based on the Chebyshev expansion

$$\operatorname{erfc} x = e^{-x^2} y(x),$$

where  $y(x) = \sum_{r=0}^{\infty} a_r T_r(t)$  and  $t = (x-3.75)/(x+3.75)$ ,  $-1 \leq t \leq +1$ .

For  $x > x_{hi}$ , where there is a danger of setting underflow, the result is returned as zero.

$$\operatorname{erfc} x = 2 - e^{-x^2} y(|x|).$$

For  $x < x_{low} < 0$ , the result is returned as 2.0 which is correct to within machine precision. The values of  $x_{hi}$  and  $x_{low}$  are given in the Users' Note for your implementation.

#### 4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
On entry: the argument x of the function.
- 2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL has been included for consistency with other routines in this

chapter.

7. Accuracy

If  $\delta$  and  $\epsilon$  are relative errors in the argument and result, respectively, then in principle

$$|\epsilon| \approx \frac{\frac{2}{e^{-x}}}{\sqrt{\pi} \operatorname{erfc} x} |\delta|.$$

That is, the relative error in the argument,  $x$ , is amplified by a

factor  $\frac{2}{e^{-x}}$  in the result.

$$\sqrt{\pi} \operatorname{erfc} x$$

The behaviour of this factor is shown in Figure 1.

Figure 1

Please see figure in printed Reference Manual

It should be noted that near  $x=0$  this factor behaves as  $\frac{2x}{\sqrt{\pi}}$

and hence the accuracy is largely determined by the machine precision. Also for large negative  $x$ , where the factor is

$\frac{2}{e^{-x}}$ , accuracy is mainly limited by machine precision.

$$\sqrt{\pi}$$

However, for large positive  $x$ , the factor becomes  $\frac{2}{e^{-2x}}$  and to an extent relative accuracy is necessarily lost. The absolute accuracy  $E$  is given by

$$E^{\sim} = \frac{-x^{2xe}}{\sqrt{\pi}(\delta)}$$

so absolute accuracy is guaranteed for all x.

8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S15 -- Approximations of Special Functions S15AEF  
 S15AEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S15AEF returns the value of the error function erfx, via the routine name.

2. Specification

```
DOUBLE PRECISION FUNCTION S15AEF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

3. Description

Evaluates the error function,

$$\operatorname{erf} x = \frac{\int_0^x e^{-t^2} dt}{\sqrt{\pi}}$$

For  $|x| \leq 2$ ,

$$\operatorname{erf} x = x \left[ a - \frac{a^3}{3r^2} T(t) \right], \text{ where } t = \frac{x}{r}, r = 0$$

For  $2 < |x| < x_{hi}$ ,

$$\operatorname{erf} x = \operatorname{sign} x \left[ 1 - \frac{e^{-x^2}}{\sqrt{\pi} r} T(t) \right], \text{ where } t = \frac{x}{r}, r = 0$$

For  $|x| \geq x_{hi}$ ,

$$\operatorname{erf} x = \operatorname{sign} x.$$

$x_{hi}$  is the value above which  $\operatorname{erf} x = \pm 1$  within machine precision.

Its value is given in the Users' Note for your implementation.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

1: X -- DOUBLE PRECISION Input  
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL

has been included for consistency with other routines in this chapter.

7. Accuracy

On a machine with approximately 11 significant figures the routine agrees with available tables to 10 figures and consistency checking with S15ADF of the relation

$$\text{erf } x + \text{erfc } x = 1.0$$

shows errors in at worst the 11th figure.

8. Further Comments

None.

9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S17 -- Approximations of Special Functions S17ACF  
 S17ACF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S17ACF returns the value of the Bessel Function  $Y(x)$ , via the routine name.

2. Specification

```
DOUBLE PRECISION FUNCTION S17ACF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Bessel Function of the second kind  $Y_0(x)$ .

0

Note:  $Y_0(x)$  is undefined for  $x \leq 0$  and the routine will fail for such arguments.

The routine is based on four Chebyshev expansions:

For  $0 < x \leq 8$ ,

$$Y_0(x) = \frac{2}{\pi} \int_0^1 \ln \frac{1}{r} \left[ a T_0\left(\frac{x}{r}\right) + b T_2\left(\frac{x}{r}\right) \right] dr, \text{ with } t = 2\left(\frac{x}{r}\right) - 1, \quad (8)$$

For  $x > 8$ ,

$$Y_0(x) = \frac{1}{\sqrt{\pi x}} \left\{ P_0(x) \sin\left(x - \frac{\pi}{4}\right) + Q_0(x) \cos\left(x - \frac{\pi}{4}\right) \right\}$$

where  $P_0(x) = \int_0^1 c T_0\left(\frac{x}{r}\right) dr$

and  $Q_0(x) = \int_0^1 d T_2\left(\frac{x}{r}\right) dr$ , with  $t = 2\left(\frac{x}{r}\right) - 1$ .

For  $x$  near zero,  $Y_0(x) \sim \frac{2}{\pi} \left( \ln\left(\frac{x}{2}\right) + \gamma \right)$ , where  $\gamma$

denotes Euler's constant. This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision.

For very large  $x$ , it becomes impossible to provide results with any reasonable accuracy (see Section 7), hence the routine fails. Such arguments contain insufficient information to determine the

phase of oscillation of  $Y_0(x)$ ; only the amplitude,  $\frac{1}{\sqrt{x}}$ , can be

determined and this is returned on soft failure. The range for which this occurs is roughly related to the machine precision: the routine will fail if  $x > 1/\text{machine precision}$  (see the Users' Note for your implementation for details).

- [2] Clenshaw C W (1962) Mathematical Tables. Chebyshev Series for Mathematical Functions. HMSO.

#### 5. Parameters

1: X -- DOUBLE PRECISION Input  
 On entry: the argument x of the function. Constraint:  $X > 0$ .  
 0.

2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 X is too large. On soft failure the routine returns the amplitude of the Y oscillation,  $\sqrt{2}/(\pi)x$ .  
 0

IFAIL= 2  
 $X \leq 0.0$ , Y is undefined. On soft failure the routine  
 0  
 returns zero.

#### 7. Accuracy

Let  $(\delta)$  be the relative error in the argument and E be the absolute error in the result. (Since Y (x) oscillates about zero,  
 0  
 absolute error and not relative error is significant, except for very small x.)

If  $(\delta)$  is somewhat larger than the machine representation

error (e.g. if  $(\delta)$  is due to data errors etc), then  $E$  and  $(\delta)$  are approximately related by

$$E \sim |xY(x)|(\delta)$$

(provided  $E$  is also within machine bounds). Figure 1 displays the behaviour of the amplification factor  $|xY(x)|$ .

1

Figure 1

Please see figure in printed Reference Manual

However, if  $(\delta)$  is of the same order as the machine representation errors, then rounding errors could make  $E$  slightly larger than the above relation predicts.

For very small  $x$ , the errors are essentially independent of  $(\delta)$  and the routine should provide relative accuracy bounded by the machine precision.

For very large  $x$ , the above relation ceases to apply. In this

region,  $Y(x) \sim \frac{1}{\sqrt{(\pi)x}} \sin\left(x - \frac{(\pi)}{4}\right)$ . The amplitude  $\frac{1}{\sqrt{(\pi)x}}$  can be calculated with reasonable accuracy for all  $x$ , but  $\sin\left(x - \frac{(\pi)}{4}\right)$  cannot. If  $x - \frac{(\pi)}{4}$  is written as  $2N(\pi) + (\theta)$  where  $N$  is an integer and  $0 \leq (\theta) < 2(\pi)$ , then  $\sin\left(x - \frac{(\pi)}{4}\right)$  is

determined by  $(\theta)$  only. If  $x \gg (\delta)$ ,  $(\theta)$  cannot be determined with any accuracy at all. Thus if  $x$  is greater than, or of the order of the inverse of machine precision, it is impossible to calculate the phase of  $Y(x)$  and the routine must

fail.

#### 8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

#### 9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S17 -- Approximations of Special Functions S17ADF  
 S17ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S17ADF returns the value of the Bessel Function Y (x), via the routine name.

2. Specification

```
DOUBLE PRECISION FUNCTION S17ADF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Bessel Function of the second kind Y (x).

Note: Y (x) is undefined for x<=0 and the routine will fail for such arguments.

The routine is based on four Chebyshev expansions:

For 0<x<=8,

$$Y(x) = \frac{1}{\pi} \int_0^x \ln t - \frac{x^2}{8} dt + \int_0^x \frac{t^2}{8} dt - \frac{1}{\pi} \int_0^x \ln t + \frac{x^2}{8} dt + \int_0^x \frac{t^2}{8} dt, \text{ with } t = \frac{2}{x} \cos^{-1} \left( \frac{2}{x} \cos \theta - 1 \right);$$

( 8)

For  $x > 8$ ,

$$Y(x) = \frac{1}{\sqrt{(\pi)x}} \left\{ \frac{1}{4} P(x) \sin\left(x - \frac{3}{4}\pi\right) + Q(x) \cos\left(x - \frac{3}{4}\pi\right) \right\}$$

$$\text{where } P(x) = \int_0^x c_r T_r(t) dt,$$

$$\text{and } Q(x) = \int_0^x d_r T_r(t) dt, \text{ with } t = 2\left(\frac{x}{8}\right) - 1.$$

For  $x$  near zero,  $Y(x) \sim \frac{1}{\sqrt{(\pi)x}}$ . This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision. For extremely small  $x$ , there is a danger of overflow in calculating  $\frac{1}{\sqrt{(\pi)x}}$  and for such arguments the routine will fail.

For very large  $x$ , it becomes impossible to provide results with any reasonable accuracy (see Section 7), hence the routine fails. Such arguments contain insufficient information to determine the

phase of oscillation of  $Y(x)$ , only the amplitude,  $\frac{1}{\sqrt{(\pi)x}}$ , can be determined and this is returned on soft failure. The range for which this occurs is roughly related to machine precision; the routine will fail if  $x > \frac{1}{\text{machine precision}}$  (see the Users' Note for your implementation for details).

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.
- [2] Clenshaw C W (1962) Mathematical Tables. Chebyshev Series for Mathematical Functions. HMSO.

5. Parameters

- 1: X -- DOUBLE PRECISION Input  
 On entry: the argument x of the function. Constraint: X > 0.  
 0.
  
- 2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 X is too large. On soft failure the routine returns the

$$\text{amplitude of the } Y_1 \text{ oscillation, } \frac{\sqrt{2}}{\sqrt{(\pi)x}}$$

IFAIL= 2  
 X <= 0.0, Y<sub>1</sub> is undefined. On soft failure the routine returns zero.

IFAIL= 3  
 X is too close to zero, there is a danger of overflow. On soft failure, the routine returns the value of Y<sub>1</sub>(x) at the smallest valid argument.

7. Accuracy

Let (delta) be the relative error in the argument and E be the absolute error in the result. (Since Y<sub>1</sub>(x) oscillates about zero, absolute error and not relative error is significant, except for very small x.)

If (delta) is somewhat larger than the machine precision (e.g. if (delta) is due to data errors etc), then E and (delta) are approximately related by:

$$E \sim |xY(x) - Y(x)|(\delta)$$

(provided  $E$  is also within machine bounds). Figure 1 displays the behaviour of the amplification factor  $|xY(x) - Y(x)|$ .

Figure 1

Please see figure in printed Reference Manual

However, if  $(\delta)$  is of the same order as machine precision, then rounding errors could make  $E$  slightly larger than the above relation predicts.

For very small  $x$ , absolute error becomes large, but the relative error in the result is of the same order as  $(\delta)$ .

For very large  $x$ , the above relation ceases to apply. In this region,  $Y(x) \sim \frac{2(\pi)}{x} \sin(x - \frac{3(\pi)}{4})$ . The amplitude  $\frac{2(\pi)}{x}$  can be calculated with reasonable accuracy for all  $x$ , but  $\sin(x - \frac{3(\pi)}{4})$  cannot. If  $x - \frac{3(\pi)}{4}$  is written as  $2N(\pi) + (\theta)$  where  $N$  is an integer and  $0 \leq (\theta) < 2(\pi)$ , then  $\sin(x - \frac{3(\pi)}{4})$  is determined by

$(\theta)$  only. If  $x > (\delta)$ ,  $(\theta)$  cannot be determined with any accuracy at all. Thus if  $x$  is greater than, or of the order of, the inverse of the machine precision, it is impossible to calculate the phase of  $Y(x)$  and the routine must fail.

1

S17 -- Approximations of Special Functions S17AEF  
 S17AEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S17AEF returns the value of the Bessel Function  $J_0(x)$ , via the routine name.

2. Specification

```
DOUBLE PRECISION FUNCTION S17AEF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Bessel Function of the first kind  $J_0(x)$ .

Note:  $J_0(-x) = J_0(x)$ , so the approximation need only consider  $x \geq 0$ .

The routine is based on three Chebyshev expansions:

For  $0 < x \leq 8$ ,

$$J_0(x) = \sum_{r=0}^2 a_r T_r(t), \text{ with } t = 2(x/8) - 1.$$

For  $x > 8$ ,

$$J_0(x) = \frac{1}{\sqrt{(\pi)x}} \left\{ P_0(x) \cos\left(x - \frac{\pi}{4}\right) - Q_0(x) \sin\left(x - \frac{\pi}{4}\right) \right\}$$

where  $P_0(x) = \sum b_r T_r(t)$ ,

$$\begin{aligned}
 & \text{and } Q(x) = \frac{1}{x} \int_0^x c T(t) dt, \text{ with } t = 2 \left( \frac{t}{x} \right)^2 - 1. \\
 & \text{where } T(t) = \sum_{r=0}^{\infty} \frac{(-1)^r}{r!} \left( \frac{t}{x} \right)^{2r}
 \end{aligned}$$

For  $x$  near zero,  $J(x) \sim 1$ . This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision.

For very large  $x$ , it becomes impossible to provide results with any reasonable accuracy (see Section 7), hence the routine fails. Such arguments contain insufficient information to determine the

phase of oscillation of  $J(x)$ ; only the amplitude,  $\frac{1}{\sqrt{(\pi)|x|}}$ , can be determined and this is returned on soft failure. The range for which this occurs is roughly related to the machine precision; the routine will fail if  $|x| > 1/\text{machine precision}$  (see the Users' Note for your implementation).

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.
- [2] Clenshaw C W (1962) Mathematical Tables. Chebyshev Series for Mathematical Functions. HMSO.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
On entry: the argument  $x$  of the function.
- 2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

X is too large. On soft failure the routine returns the

$$\text{amplitude of the } J_0 \text{ oscillation, } \frac{\sqrt{2}}{\sqrt{(\pi)|x|}}.$$

7. Accuracy

Let  $(\delta)$  be the relative error in the argument and E be the absolute error in the result. (Since  $J_0(x)$  oscillates about zero, absolute error and not relative error is significant.)

If  $(\delta)$  is somewhat larger than the machine precision (e.g. if  $(\delta)$  is due to data errors etc), then E and  $(\delta)$  are approximately related by:

$$E \sim |x J_0(x)| (\delta)$$

(provided E is also within machine bounds). Figure 1 displays the behaviour of the amplification factor  $|x J_0(x)|$ .

Figure 1

Please see figure in printed Reference Manual

However, if  $(\delta)$  is of the same order as machine precision, then rounding errors could make E slightly larger than the above relation predicts.

For very large x, the above relation ceases to apply. In this

region,  $J_0(x) \sim \frac{\sqrt{2}}{\sqrt{(\pi)|x|}} \cos(x - \frac{(\pi)}{4})$ . The amplitude

$\frac{\sqrt{2}}{\sqrt{(\pi)|x|}}$  can be calculated with reasonable accuracy for all x but  $\cos(x - \frac{(\pi)}{4})$  cannot. If  $x - \frac{(\pi)}{4}$  is written as  $2N(\pi) + (\theta)$  where N is an integer and  $0 \leq (\theta) < 2(\pi)$ ,

$(\pi)$  -1  
 then  $\cos(x - \frac{\pi}{4})$  is determined by  $(\theta)$  only. If  $x \sim \delta$  ,  
 $(\frac{\pi}{4})$   
 $(\theta)$  cannot be determined with any accuracy at all. Thus if  $x$   
 is greater than, or of the order of, the inverse of the machine  
 precision, it is impossible to calculate the phase of  $J(x)$  and  
0  
 the routine must fail.

### 8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S17 -- Approximations of Special Functions S17AFF  
 S17AFF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S17AFF returns the value of the Bessel Function  $J(x)$ , via the  
1  
 routine name.

### 2. Specification

DOUBLE PRECISION FUNCTION S17AFF (X, IFAIL)  
 INTEGER IFAIL  
 DOUBLE PRECISION X

### 3. Description

This routine evaluates an approximation to the Bessel Function of the first kind  $J(x)$ .

Note:  $J(-x) = -J(x)$ , so the approximation need only consider  $x \geq 0$

The routine is based on three Chebyshev expansions:

For  $0 < x \leq 8$ ,

$$J(x) = \sum_{r=0}^8 a_r T_r(t), \text{ with } t = 2(x/8)^2 - 1.$$

For  $x > 8$ ,

$$J(x) = \frac{1}{\sqrt{\pi}} \left\{ \frac{1}{2} P(x) \cos\left(x - \frac{3\pi}{4}\right) - Q(x) \sin\left(x - \frac{3\pi}{4}\right) \right\}$$

where  $P(x) = \sum_{r=0}^8 b_r T_r(t)$ ,

and  $Q(x) = \sum_{r=0}^8 c_r T_r(t)$ , with  $t = 2(x/8)^2 - 1$ .

For  $x$  near zero,  $J(x) \sim \frac{x}{2}$ . This approximation is used when  $x$  is

sufficiently small for the result to be correct to machine precision.

For very large  $x$ , it becomes impossible to provide results with any reasonable accuracy (see Section 7), hence the routine fails. Such arguments contain insufficient information to determine the

phase of oscillation of  $J(x)$ ; only the amplitude,  $\frac{1}{\sqrt{\pi|x|}}$ , can be determined and this is returned on soft failure. The range for which this occurs is roughly related to the machine precision; the routine will fail if  $|x| > 1/\text{machine precision}$  (see the Users' Note for your implementation for details).

#### 5. Parameters

1: X -- DOUBLE PRECISION Input  
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

X is too large. On soft failure the routine returns the

amplitude of the J<sub>1</sub> oscillation,  $\frac{\sqrt{2}}{\sqrt{(\pi)|x|}}$ .

#### 7. Accuracy

Let  $(\delta)$  be the relative error in the argument and E be the absolute error in the result. (Since J<sub>1</sub>(x) oscillates about zero, absolute error and not relative error is significant.)

If  $(\delta)$  is somewhat larger than machine precision (e.g. if  $(\delta)$  is due to data errors etc), then E and  $(\delta)$  are approximately related by:

$$E \approx |x J_0(x) - J_1(x)| (\delta)$$

(provided E is also within machine bounds). Figure 1 displays the behaviour of the amplification factor  $|x J_0(x) - J_1(x)|$ .

0      1

Figure 1

Please see figure in printed Reference Manual

However, if  $(\delta)$  is of the same order as machine precision, then rounding errors could make  $E$  slightly larger than the above relation predicts.

For very large  $x$ , the above relation ceases to apply. In this

$$\text{region, } J_1(x) \sim \frac{1}{\sqrt{(\pi)|x|}} \cos\left(x - \frac{3(\pi)}{4}\right). \text{ The amplitude}$$

$\frac{1}{\sqrt{(\pi)|x|}}$  can be calculated with reasonable accuracy for all  $x$

but  $\cos\left(x - \frac{3(\pi)}{4}\right)$  cannot. If  $x - \frac{3(\pi)}{4}$  is written as

$2N(\pi) + (\theta)$  where  $N$  is an integer and  $0 \leq (\theta) < 2(\pi)$ , then  $\cos\left(x - \frac{3(\pi)}{4}\right)$  is determined by  $(\theta)$  only. If  $x \sim (\delta)$ ,

$(\theta)$  cannot be determined with any accuracy at all. Thus if  $x$  is greater than, or of the order of, machine precision, it is impossible to calculate the phase of  $J_1(x)$  and the routine must fail.

8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S17AGF returns a value for the Airy function,  $Ai(x)$ , via the routine name.

### 2. Specification

```
DOUBLE PRECISION FUNCTION S17AGF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

### 3. Description

This routine evaluates an approximation to the Airy function,  $Ai(x)$ . It is based on a number of Chebyshev expansions:

For  $x < -5$ ,

$$Ai(x) = \frac{a(t)\sin z - b(t)\cos z}{1/4 (-x)}$$

where  $z = \frac{(\pi)^{2/3}}{4} - \sqrt{-x}$ , and  $a(t)$  and  $b(t)$  are expansions in the variable  $t = -2(-x)^{-1/3}$ .

For  $-5 \leq x \leq 0$ ,

$$Ai(x) = f(t) - xg(t),$$

where  $f$  and  $g$  are expansions in  $t = -2(-x)^{-1/3}$ .

For  $0 < x < 4.5$ ,

$$Ai(x) = e^{-3x/2} y(t),$$

where y is an expansion in  $t=4x/9-1$ .

For  $4.5 \leq x < 9$ ,

$$Ai(x) = e^{-5x/2} u(t),$$

where u is an expansion in  $t=4x/9-3$ .

For  $x \geq 9$ ,

$$Ai(x) = \frac{e^{-z} v(t)}{x^{1/4}}$$

$$\text{where } z = \frac{2}{3} \sqrt{x} \text{ and } v \text{ is an expansion in } t = 2\left(\frac{z}{x}\right) - 1. \tag{18}$$

For  $|x| <$  the machine precision, the result is set directly to  $Ai(0)$ . This both saves time and guards against underflow in intermediate calculations.

For large negative arguments, it becomes impossible to calculate the phase of the oscillatory function with any precision and so

the routine must fail. This occurs if  $x < \left(\frac{2}{3}\right)^{2/3} \epsilon$ , where  $\epsilon$  (epsilon) is the machine precision.

For large positive arguments, where  $Ai$  decays in an essentially exponential manner, there is a danger of underflow so the routine must fail.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input  
 On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 X is too large and positive. On soft failure, the routine returns zero.

IFAIL= 2  
 X is too large and negative. On soft failure, the routine returns zero.

## 7. Accuracy

For negative arguments the function is oscillatory and hence absolute error is the appropriate measure. In the positive region the function is essentially exponential-like and here relative error is appropriate. The absolute error, E, and the relative error, (epsilon), are related in principle to the relative error in the argument, (delta), by

$$E \sim |x A_i'(x)| (\delta), \quad (\epsilon) \sim \frac{|x A_i'(x)|}{|A_i(x)|} (\delta).$$

In practice, approximate equality is the best that can be expected. When (delta), (epsilon) or E is of the order of the machine precision, the errors in the result will be somewhat larger.

For small x, errors are strongly damped by the function and hence will be bounded by the machine precision.

For moderate negative x, the error behaviour is oscillatory but the amplitude of the error grows like

$$\text{amplitude} \left( \frac{E}{(\delta)} \right) \sim \frac{|x|^{5/4}}{\sqrt{(\pi)}}.$$

However the phase error will be growing roughly like  $-\sqrt[3]{|x|}$  and hence all accuracy will be lost for large negative arguments due to the impossibility of calculating sin and cos to any

$$\text{accuracy if } -\sqrt[3]{|x|} > \frac{1}{3(\text{delta})}.$$

For large positive arguments, the relative error amplification is considerable:

$$\frac{(\text{epsilon})}{3(\text{delta})} \sim \sqrt[3]{x}.$$

This means a loss of roughly two decimal places accuracy for arguments in the region of 20. However very large arguments are not possible due to the danger of setting underflow and so the errors are limited in practice.

8. Further Comments

None.

9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S17 -- Approximations of Special Functions S17AHF  
 S17AHF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S17AHF returns a value of the Airy function,  $Bi(x)$ , via the routine name.

## 2. Specification

```
DOUBLE PRECISION FUNCTION S17AHF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

## 3. Description

This routine evaluates an approximation to the Airy function  $Bi(x)$ . It is based on a number of Chebyshev expansions.

For  $x < -5$ ,

$$Bi(x) = \frac{a(t)\cos z + b(t)\sin z}{(-x)^{1/4}}$$

where  $z = \frac{(\pi)^{2/3}}{4} - \sqrt{-x}$  and  $a(t)$  and  $b(t)$  are expansions in the variable  $t = -2(-x)^{-1/3}$ .

For  $-5 \leq x < 0$ ,

$$Bi(x) = \sqrt[3]{f(t) + xg(t)}$$

where  $f$  and  $g$  are expansions in  $t = -2(-x)^{-1/3}$ .

For  $0 < x < 4.5$ ,

$$Bi(x) = e^{11x/8} y(t)$$

where  $y$  is an expansion in  $t = 4x/9 - 1$ .

For  $4.5 \leq x < 9$ ,

$$Bi(x) = e^{5x/2} v(t),$$

where v is an expansion in  $t=4x/9-3$ .

For  $x \geq 9$ ,

$$Bi(x) = \frac{e^{u(t)}}{x^{1/4}},$$

$$\text{where } z = -\sqrt[3]{x} \text{ and } u \text{ is an expansion in } t = 2\left(\frac{z}{3}\right) - 1. \tag{18}$$

For  $|x| <$  the machine precision, the result is set directly to  $Bi(0)$ . This both saves time and avoids possible intermediate underflows.

For large negative arguments, it becomes impossible to calculate the phase of the oscillating function with any accuracy so the

routine must fail. This occurs if  $x < -\left(\frac{\epsilon^{2/3}}{2(\epsilon)}\right)$ , where  $\epsilon$  (epsilon) is the machine precision.

For large positive arguments, there is a danger of causing overflow since  $Bi$  grows in an essentially exponential manner, so the routine must fail.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

- 1: X -- DOUBLE PRECISION Input  
On entry: the argument x of the function.
- 2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

X is too large and positive. On soft failure, the routine returns zero.

IFAIL= 2

X is too large and negative. On soft failure, the routine returns zero.

## 7. Accuracy

For negative arguments the function is oscillatory and hence absolute error is the appropriate measure. In the positive region the function is essentially exponential-like and here relative error is appropriate. The absolute error, E, and the relative error, (epsilon), are related in principle to the relative error in the argument, (delta), by

$$E \sim |x \text{Bi}'(x)| (\delta), \quad (\epsilon) \sim \frac{|x \text{Bi}'(x)|}{|\text{Bi}(x)|} (\delta).$$

In practice, approximate equality is the best that can be expected. When (delta), (epsilon) or E is of the order of the machine precision, the errors in the result will be somewhat larger.

For small x, errors are strongly damped and hence will be bounded essentially by the machine precision.

For moderate to large negative x, the error behaviour is clearly oscillatory but the amplitude of the error grows like amplitude

$$\left( \frac{E}{(\delta)} \right) \sim |x|^{5/4} \sqrt{\pi}.$$

However the phase error will be growing roughly as  $-\frac{2}{3} \sqrt{|x|}$  and

hence all accuracy will be lost for large negative arguments.

This is due to the impossibility of calculating sin and cos to

$$\text{any accuracy if } \frac{2}{3} \sqrt{|x|} > \frac{1}{(\text{delta})}.$$

For large positive arguments, the relative error amplification is considerable:

$$\frac{(\text{epsilon})}{(\text{delta})} \sqrt[3]{x}.$$

This means a loss of roughly two decimal places accuracy for arguments in the region of 20. However very large arguments are not possible due to the danger of causing overflow and errors are therefore limited in practice.

8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S17 -- Approximations of Special Functions S17AJF  
 S17AJF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S17AJF returns a value of the derivative of the Airy function

$Ai(x)$ , via the routine name.

## 2. Specification

```
DOUBLE PRECISION FUNCTION S17AJF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

## 3. Description

This routine evaluates an approximation to the derivative of the Airy function  $Ai(x)$ . It is based on a number of Chebyshev expansions.

For  $x < -5$ ,

$$Ai'(x) = \sqrt{-x} [a(t) \cos z + \frac{b(t)}{(zeta)^3} \sin z],$$

where  $z = \frac{\pi}{4} + (zeta)$ ,  $(zeta) = \frac{2}{3} \sqrt{-x}$  and  $a(t)$  and  $b(t)$  are expansions in variable  $t = -2 \left( \frac{-}{x} \right)^{-1}$ .

For  $-5 \leq x \leq 0$ ,

$$Ai'(x) = x f(t) - g(t),$$

where  $f$  and  $g$  are expansions in  $t = -2 \left( \frac{-}{x} \right)^{-1}$ .

For  $0 < x < 4.5$ ,

$$Ai'(x) = e^{-11x/8} y(t),$$

where  $y(t)$  is an expansion in  $t = 4 \left( \frac{-}{x} \right)^{-1}$ .

For  $4.5 \leq x < 9$ ,

$$Ai'(x) = e^{-5x/2} v(t),$$

where  $v(t)$  is an expansion in  $t = 4 \left( \frac{x}{9} \right)^{-3}$ .

For  $x \geq 9$ ,

$$Ai'(x) = \sqrt{-x} e^{-z} u(t),$$

where  $z = \frac{2}{3} \sqrt{x}$  and  $u(t)$  is an expansion in  $t = 2 \left( \frac{z}{3} \right)^{-1}$ .

For  $|x| <$  the square of the machine precision, the result is set directly to  $Ai'(0)$ . This both saves time and avoids possible intermediate underflows.

For large negative arguments, it becomes impossible to calculate a result for the oscillating function with any accuracy and so

the routine must fail. This occurs for  $x < - \left( \frac{\epsilon}{\sqrt{\pi}} \right)^{4/7}$ , where  $\epsilon$  is the machine precision.

For large positive arguments, where  $Ai'$  decays in an essentially exponential manner, there is a danger of underflow so the routine must fail.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

- 1: X -- DOUBLE PRECISION Input  
On entry: the argument x of the function.
- 2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
On exit: IFAIL = 0 unless the routine detects an error (see

Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

X is too large and positive. On soft failure, the routine returns zero.

IFAIL= 2

X is too large and negative. On soft failure, the routine returns zero.

## 7. Accuracy

For negative arguments the function is oscillatory and hence absolute error is the appropriate measure. In the positive region the function is essentially exponential in character and here relative error is needed. The absolute error, E, and the relative error, (epsilon), are related in principle to the relative error in the argument, (delta), by

$$E \sim |x \operatorname{Ai}(x)| (\delta)^2 \quad (\epsilon) \sim \frac{|x \operatorname{Ai}(x)|^2}{| \operatorname{Ai}'(x) |} (\delta).$$

In practice, approximate equality is the best that can be expected. When (delta), (epsilon) or E is of the order of the machine precision, the errors in the result will be somewhat larger.

For small x, positive or negative, errors are strongly attenuated by the function and hence will be roughly bounded by the machine precision.

For moderate to large negative x, the error, like the function, is oscillatory; however the amplitude of the error grows like

$$\frac{|x|^{7/4}}{\sqrt{\pi}}.$$

Therefore it becomes impossible to calculate the function with

any accuracy if  $|x| > \frac{7/4 \sqrt{\pi}}{(\text{delta})}$ .

For large positive x, the relative error amplification is considerable:

$\frac{(\text{epsilon})}{(\text{delta})} \sim \frac{1}{\sqrt{x}}$ .

However, very large arguments are not possible due to the danger of underflow. Thus in practice error amplification is limited.

8. Further Comments

None.

9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S17 -- Approximations of Special Functions S17AKF  
 S17AKF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S17AKF returns a value for the derivative of the Airy function Bi(x), via the routine name.

2. Specification

DOUBLE PRECISION FUNCTION S17AKF (X, IFAIL)  
 INTEGER IFAIL  
 DOUBLE PRECISION X

## 3. Description

This routine calculates an approximate value for the derivative of the Airy function  $Bi(x)$ . It is based on a number of Chebyshev expansions.

For  $x < -5$ ,

$$Bi'(x) = \sqrt{-x} \left[ -a(t) \sin z + \frac{b(t)}{(zeta)} \cos z \right],$$

where  $z = \frac{\pi}{4} + (zeta)$ ,  $(zeta) = \frac{2}{3} \sqrt{-x}$  and  $a(t)$  and  $b(t)$  are

expansions in the variable  $t = -2 \left( \frac{5}{x} \right) - 1$ .

For  $-5 \leq x < 0$ ,

$$Bi'(x) = \sqrt[3]{x} \left( f(t) + g(t) \right),$$

where  $f$  and  $g$  are expansions in  $t = -2 \left( \frac{5}{x} \right) - 1$ .

For  $0 < x < 4.5$ ,

$$Bi'(x) = e^{3x/2} y(t),$$

where  $y(t)$  is an expansion in  $t = 4x/9 - 1$ .

For  $4.5 \leq x < 9$ ,

$$Bi'(x) = e^{21x/8} u(t),$$

where  $u(t)$  is an expansion in  $t = 4x/9 - 3$ .

For  $x \geq 9$ ,

$$Bi'(x) = \sqrt{x} e^z v(t),$$

$$\text{where } z = \frac{-\sqrt{x}}{3} \text{ and } v(t) \text{ is an expansion in } t = 2\left(\frac{z}{3}\right)^{-1}. \quad (18)$$

For  $|x| <$  the square of the machine precision, the result is set directly to  $Bi'(0)$ . This saves time and avoids possible underflows in calculation.

For large negative arguments, it becomes impossible to calculate a result for the oscillating function with any accuracy so the

routine must fail. This occurs for  $x < -\left(\frac{\sqrt{\pi}}{\epsilon}\right)^{4/7}$ , where  $\epsilon$  (epsilon) is the machine precision.

For large positive arguments, where  $Bi'$  grows in an essentially exponential manner, there is a danger of overflow so the routine must fail.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

- 1: X -- DOUBLE PRECISION Input  
On entry: the argument x of the function.
- 2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
X is too large and positive. On soft failure the routine returns zero.

IFAIL= 2  
X is too large and negative. On soft failure the routine

returns zero.

### 7. Accuracy

For negative arguments the function is oscillatory and hence absolute error is appropriate. In the positive region the function has essentially exponential behaviour and hence relative error is needed. The absolute error,  $E$ , and the relative error (epsilon), are related in principle to the relative error in the argument ( $\delta$ ), by

$$E \sim |x \operatorname{Bi}(x)| (\delta)^2 \quad (\epsilon) \sim \frac{|x \operatorname{Bi}(x)|}{|\operatorname{Bi}'(x)|} (\delta).$$

In practice, approximate equality is the best that can be expected. When ( $\delta$ ), ( $\epsilon$ ) or  $E$  is of the order of the machine precision, the errors in the result will be somewhat larger.

For small  $x$ , positive or negative, errors are strongly attenuated by the function and hence will effectively be bounded by the machine precision.

For moderate to large negative  $x$ , the error is, like the function, oscillatory. However, the amplitude of the absolute

error grows like  $|x|^{7/4}$ . Therefore it becomes impossible to

$$\sqrt[7]{\pi}$$

calculate the function with any accuracy if  $|x| > \frac{\sqrt[7]{\pi}}{\delta}$ .

For large positive  $x$ , the relative error amplification is

considerable:  $\frac{(\epsilon)}{\delta} \sim \sqrt[3]{x}$ . However, very large arguments are

not possible due to the danger of overflow. Thus in practice the actual amplification that occurs is limited.

### 8. Further Comments

None.

9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S17 -- Approximations of Special Functions S17DCF  
 S17DCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S17DCF returns a sequence of values for the Bessel functions  $Y_{\nu}(z)$  for complex z, non-negative (nu) and n=0,1,...,N-1,  $(\nu)+n$  with an option for exponential scaling.

2. Specification

```

SUBROUTINE S17DCF (FNU, Z, N, SCALE, CY, NZ, CWRK, IFAIL)
INTEGER          N, NZ, IFAIL
DOUBLE PRECISION FNU
COMPLEX(KIND(1.0D0)) Z, CY(N), CWRK(N)
CHARACTER*1      SCALE
    
```

3. Description

This subroutine evaluates a sequence of values for the Bessel function  $Y_{\nu}(z)$ , where z is complex,  $-(\pi) < \arg z \leq (\pi)$ , and  $(\nu)$  is the real, non-negative order. The N-member sequence is generated for orders  $(\nu)$ ,  $(\nu)+1, \dots, (\nu)+N-1$ . Optionally, the sequence is scaled by the factor  $e^{-|\operatorname{Im} z|}$ .

Note: although the routine may not be called with (nu) less than zero, for negative orders the formula  $Y_{-\nu}(z) = Y_{\nu}(z) \cos((\pi)(\nu)) + J_{\nu}(z) \sin((\pi)(\nu))$  may be used

(for the Bessel function  $J_{(\text{nu})}(z)$ , see S17DEF).

The routine is derived from the routine CBESY in Amos [2]. It is

based on the relation 
$$Y_{(\text{nu})}^{(2)}(z) = \frac{H_{(\text{nu})}^{(1)}(z) - H_{(\text{nu})}^{(2)}(z)}{2i}$$
, where  $H_{(\text{nu})}^{(1)}(z)$

and  $H_{(\text{nu})}^{(2)}(z)$  are the Hankel functions of the first and second kinds respectively (see S17DLF).

When N is greater than 1, extra values of  $Y_{(\text{nu})}(z)$  are computed using recurrence relations.

For very large  $|z|$  or  $((\text{nu})+N-1)$ , argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller  $|z|$  or  $((\text{nu})+N-1)$ , the computation is performed but results are accurate to less than half of machine precision. If  $|z|$  is very small, near the machine underflow threshold, or  $((\text{nu})+N-1)$  is too large, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

#### 5. Parameters

- 1: FNU -- DOUBLE PRECISION Input  
On entry: the order, (nu), of the first member of the sequence of functions. Constraint: FNU >= 0.0.
- 2: Z -- COMPLEX(KIND(1.0D0)) Input  
On entry: the argument, z, of the functions. Constraint: Z /= (0.0, 0.0).
- 3: N -- INTEGER Input  
On entry: the number, N, of members required in the sequence  $Y_{(\text{nu})}(z), Y_{(\text{nu})+1}(z), \dots, Y_{(\text{nu})+N-1}(z)$ . Constraint: N >= 1.

- 4: SCALE -- CHARACTER\*1 Input  
 On entry: the scaling option.  
  
 If SCALE = 'U', the results are returned unscaled.  
  
 If SCALE = 'S', the results are returned scaled by the  
 $-\text{Im}z$   
 factor  $e$ . Constraint: SCALE = 'U' or 'S'.
- 5: CY(N) -- COMPLEX(KIND(1.0D)) array Output  
 On exit: the N required function values: CY(i) contains  
 $Y$   
 $(z)$ , for  $i=1,2,\dots,N$ .  
 $(\text{nu})+i-1$
- 6: NZ -- INTEGER Output  
 On exit: the number of components of CY that are set to zero  
 due to underflow. The positions of such components in the  
 array CY are arbitrary.
- 7: CWRK(N) -- COMPLEX(KIND(1.0D)) array Workspace
- 8: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not  
 familiar with this parameter (described in the Essential  
 Introduction) the recommended value is 0.  
  
 On exit: IFAIL = 0 unless the routine detects an error (see  
 Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are  
 output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry FNU < 0.0,

or  $Z = (0.0, 0.0)$ ,

or  $N < 1$ ,

or SCALE /= 'U' or 'S'.

IFAIL= 2

No computation has been performed due to the likelihood of  
 overflow, because  $\text{ABS}(Z)$  is less than a machine-dependent  
 threshold value (given in the Users' Note for your

implementation).

IFAIL= 3

No computation has been performed due to the likelihood of overflow, because  $FNU + N - 1$  is too large - how large depends on  $Z$  as well as the overflow threshold of the machine.

IFAIL= 4

The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the results returned by S17DCF are accurate to less than half of machine precision. This error exit may occur if either  $ABS(Z)$  or  $FNU + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 5

No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by S17DCF would be lost. This error exit may occur if either  $ABS(Z)$  or  $FNU + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 6

No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S17DCF would have caused overflow or underflow.

## 7. Accuracy

All constants in subroutine S17DCF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used  $t$ , then clearly the maximum number of correct digits in the results obtained is limited by  $p = \min(t, 18)$ . Because of errors in argument reduction when computing elementary functions inside S17DCF, the actual number of correct digits is limited, in general, by  $p - s$ , where  $s = \max(1, \log_{10} |z|, \log_{10} (\nu))$  represents the number of digits

lost due to the argument reduction. Thus the larger the values of  $|z|$  and  $(\nu)$ , the less the precision in the result. If S17DCF is called with  $N > 1$ , then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S17DCF with different base values of  $(\nu)$  and different  $N$ , the computed values may not agree exactly.

Empirical tests with modest values of (nu) and z have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

8. Further Comments

The time taken by the routine for a call of S17DCF is approximately proportional to the value of N, plus a constant. In general it is much cheaper to call S17DCF with N greater than 1, rather than to make N separate calls to S17DCF.

Paradoxically, for some values of z and (nu), it is cheaper to call S17DCF with a larger value of N than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different N, and the costs in each region may differ greatly.

Note that if the function required is  $Y_0(x)$  or  $Y_1(x)$ , i.e., (nu) = 0.0 or 1.0, where x is real and positive, and only a single unscaled function value is required, then it may be much cheaper to call S17ACF or S17ADF respectively.

9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the order FNU, the second is a complex value for the argument, Z, and the third is a value for the parameter SCALE. The program calls the routine with N = 2 to evaluate the function for orders FNU and FNU + 1, and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S17 -- Approximations of Special Functions S17DEF  
 S17DEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

S17DEF returns a sequence of values for the Bessel functions  $J_{(\nu)+n}(z)$  for complex  $z$ , non-negative  $(\nu)$  and  $n=0,1,\dots,N-1$ , with an option for exponential scaling.

## 2. Specification

```

SUBROUTINE S17DEF (FNU, Z, N, SCALE, CY, NZ, IFAIL)
  INTEGER          N, NZ, IFAIL
  DOUBLE PRECISION FNU
  COMPLEX(KIND(1.0D0)) Z, CY(N)
  CHARACTER*1      SCALE

```

## 3. Description

This subroutine evaluates a sequence of values for the Bessel function  $J_{(\nu)}(z)$ , where  $z$  is complex,  $-(\pi) < \arg z \leq (\pi)$ , and  $(\nu)$

$(\nu)$  is the real, non-negative order. The  $N$ -member sequence is generated for orders  $(\nu)$ ,  $(\nu)+1, \dots, (\nu)+N-1$ . Optionally, the sequence is scaled by the factor  $e^{-|\operatorname{Im} z|}$ .

Note: although the routine may not be called with  $(\nu)$  less than zero, for negative orders the formula

$J_{-(\nu)}(z) = J_{(\nu)}(z) \cos((\pi)(\nu)) - Y_{(\nu)}(z) \sin((\pi)(\nu))$  may be used (for the Bessel function  $Y_{(\nu)}(z)$ , see S17DCF).

The routine is derived from the routine CBESJ in Amos [2]. It is based on the relations  $J_{(\nu)}(z) = e^{(\nu)(\pi)i/2} I_{(\nu)}(-iz)$ ,  $\operatorname{Im} z \geq 0.0$

and  $J_{(\nu)}(z) = e^{-(\nu)(\pi)i/2} I_{(\nu)}(iz)$ ,  $\operatorname{Im} z < 0.0$ .

The Bessel function  $I_{(\nu)}(z)$  is computed using a variety of techniques depending on the region under consideration.

When  $N$  is greater than 1, extra values of  $J_{(\nu)}(z)$  are computed using recurrence relations.

For very large  $|z|$  or  $((\nu)+N-1)$ , argument reduction will cause total loss of accuracy, and so no computation is performed. For

slightly smaller  $|z|$  or  $((nu)+N-1)$ , the computation is performed but results are accurate to less than half of machine precision. If  $\text{Im } z$  is large, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

#### 4. References

- [2] Amos D E (1986) Algorithm 644: A Portable Package for Bessel Functions of a Complex Argument and Nonnegative Order. ACM Trans. Math. Softw. 12 265--273.

#### 5. Parameters

- 1: FNU -- DOUBLE PRECISION Input  
 On entry: the order, (nu), of the first member of the sequence of functions. Constraint: FNU  $\geq$  0.0.
- 2: Z -- COMPLEX(KIND(1.0D0)) Input  
 On entry: the argument z of the functions.
- 3: N -- INTEGER Input  
 On entry: the number, N, of members required in the sequence  $J_{(nu)}(z), J_{(nu)+1}(z), \dots, J_{(nu)+N-1}(z)$ . Constraint: N  $\geq$  1.
- 4: SCALE -- CHARACTER\*1 Input  
 On entry: the scaling option.  
 If SCALE = 'U', the results are returned unscaled.  
 If SCALE = 'S', the results are returned scaled by the factor  $e^{-|\text{Im}z|}$ .  
 Constraint: SCALE = 'U' or 'S'.
- 5: CY(N) -- COMPLEX(KIND(1.0D)) array Output  
 On exit: the N required function values: CY(i) contains  $J_{(nu)+i-1}(z)$ , for  $i=1,2,\dots,N$ .
- 6: NZ -- INTEGER Output  
 On exit: the number of components of CY that are set to zero due to underflow. If NZ  $>$  0, then elements CY(N-NZ+1), CY(N-NZ+2), ..., CY(N) are set to zero.
- 7: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not

familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry FNU < 0.0,

or N < 1,

or SCALE /= 'U' or 'S'.

IFAIL= 2

No computation has been performed due to the likelihood of overflow, because  $\text{Im } Z$  is larger than a machine-dependent threshold value (given in the Users' Note for your implementation). This error exit can only occur when SCALE = 'U'.

IFAIL= 3

The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the results returned by S17DEF are accurate to less than half of machine precision. This error exit may occur if either  $\text{ABS}(Z)$  or  $\text{FNU} + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 4

No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by S17DEF would be lost. This error exit may occur when either  $\text{ABS}(Z)$  or  $\text{FNU} + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 5

No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S17DEF would have caused overflow or underflow.

## 7. Accuracy

All constants in subroutine S17DEF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used  $t$ , then clearly the maximum number of correct digits in the results obtained is limited by  $p = \min(t, 18)$ . Because of errors in argument reduction when computing elementary functions inside S17DEF, the actual number of correct digits is limited, in general, by  $p - s$ , where  $s = \max(1, \log_{10}(|z|), \log_{10}(\text{nu}))$  represents the number of digits lost due to the argument reduction. Thus the larger the values of  $|z|$  and  $(\text{nu})$ , the less the precision in the result. If S17DEF is called with  $N > 1$ , then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S17DEF with different base values of  $(\text{nu})$  and different  $N$ , the computed values may not agree exactly. Empirical tests with modest values of  $(\text{nu})$  and  $z$  have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

## 8. Further Comments

The time taken by the routine for a call of S17DEF is approximately proportional to the value of  $N$ , plus a constant. In general it is much cheaper to call S17DEF with  $N$  greater than 1, rather than to make  $N$  separate calls to S17DEF.

Paradoxically, for some values of  $z$  and  $(\text{nu})$ , it is cheaper to call S17DEF with a larger value of  $N$  than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different  $N$ , and the costs in each region may differ greatly.

Note that if the function required is  $J_0(x)$  or  $J_1(x)$ , i.e.,  $(\text{nu}) = 0$  or  $1$ , where  $x$  is real and positive, and only a single unscaled function value is required, then it may be much cheaper to call S17AEF or S17AFF respectively.

## 9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the order FNU, the second is a complex value for the argument,  $Z$ , and the third is a value for the parameter SCALE.

The program calls the routine with  $N = 2$  to evaluate the function for orders  $FNU$  and  $FNU + 1$ , and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S17 -- Approximations of Special Functions S17DGF  
 S17DGF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S17DGF returns the value of the Airy function  $Ai(z)$  or its derivative  $Ai'(z)$  for complex  $z$ , with an option for exponential scaling.

### 2. Specification

```

SUBROUTINE S17DGF (DERIV, Z, SCALE, AI, NZ, IFAIL)
  INTEGER          NZ, IFAIL
  COMPLEX(KIND(1.0D0)) Z, AI
  CHARACTER*1     DERIV, SCALE

```

### 3. Description

This subroutine returns a value for the Airy function  $Ai(z)$  or its derivative  $Ai'(z)$ , where  $z$  is complex,  $-(\pi) < \arg z \leq (\pi)$ .

Optionally, the value is scaled by the factor  $e^{2z\sqrt{z/3}}$ .

The routine is derived from the routine CAIRY in Amos [2]. It is

$$\sqrt{z}K \quad (w) \qquad -zK \quad (w)$$

$$1/3 \qquad \qquad \qquad 2/3$$

based on the relations  $Ai(z) = \frac{\sqrt{z}K(w)}{1/3}$ , and  $Ai'(z) = \frac{-zK(w)}{2/3}$ ,

$(\pi)^{1/3}$  $(\pi)^{1/3}$ 

where  $K_{\nu}$  is the modified Bessel function and  $w=2z^{1/3}$ .

For very large  $|z|$ , argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller  $|z|$ , the computation is performed but results are accurate to less than half of machine precision. If  $\text{Re } w$  is too large, and the unscaled function is required, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

- [2] Amos D E (1986) Algorithm 644: A Portable Package for Bessel Functions of a Complex Argument and Nonnegative Order. ACM Trans. Math. Softw. 12 265--273.

#### 5. Parameters

- 1: DERIV -- CHARACTER\*1 Input  
 On entry: specifies whether the function or its derivative is required.  
 If DERIV = 'F',  $A_i(z)$  is returned.  
 If DERIV = 'D',  $A_i'(z)$  is returned.  
 Constraint: DERIV = 'F' or 'D'.
- 2: Z -- COMPLEX(KIND(1.0D0)) Input  
 On entry: the argument  $z$  of the function.
- 3: SCALE -- CHARACTER\*1 Input  
 On entry: the scaling option.  
 If SCALE = 'U', the result is returned unscaled.  
 If SCALE = 'S', the result is returned scaled by the factor  

$$e^{-2z^{1/3}}$$
 . Constraint: SCALE = 'U' or 'S'.
- 4: AI -- COMPLEX(KIND(1.0D0)) Output  
 On exit: the required function or derivative value.

5: NZ -- INTEGER Output  
 On exit: NZ indicates whether or not AI is set to zero due to underflow. This can only occur when SCALE = 'U'.

If NZ = 0, AI is not set to zero.

If NZ = 1, AI is set to zero.

6: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry DERIV /= 'F' or 'D'.

or SCALE /= 'U' or 'S'.

IFAIL= 2

No computation has been performed due to the likelihood of

overflow, because  $\text{Re } w$  is too large, where  $w=2Z\sqrt{Z/3}$  -- how large depends on  $Z$  and the overflow threshold of the machine. This error exit can only occur when SCALE = 'U'.

IFAIL= 3

The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the result returned by S17DGF is accurate to less than half of machine precision. This error exit may occur if  $\text{ABS}(Z)$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 4

No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in the result returned by S17DGF would be lost. This error exit may occur if  $\text{ABS}(Z)$  is greater than a machine-dependent threshold value (given in the Users' Note

S17 -- Approximations of Special Functions S17DHF  
 S17DHF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S17DHF returns the value of the Airy function  $Bi(z)$  or its derivative  $Bi'(z)$  for complex  $z$ , with an option for exponential scaling.

### 2. Specification

```

SUBROUTINE S17DHF (DERIV, Z, SCALE, BI, IFAIL)
  INTEGER          IFAIL
  COMPLEX(KIND(1.0D0)) Z, BI
  CHARACTER*1      DERIV, SCALE

```

### 3. Description

This subroutine returns a value for the Airy function  $Bi(z)$  or its derivative  $Bi'(z)$ , where  $z$  is complex,  $-\pi < \arg z \leq \pi$ .

Optionally, the value is scaled by the factor  $e^{-|\operatorname{Re}(2z\sqrt{z/3})|}$ .

The routine is derived from the routine CBIRY in Amos [2]. It is

based on the relations  $Bi(z) = \frac{\sqrt{z}}{\sqrt{3}} (I_{-1/3}(w) + I_{1/3}(w))$ , and

$$Bi'(z) = \frac{z}{\sqrt{3}} (I_{-2/3}(w) + I_{2/3}(w)),$$

where  $I_{\nu}$  is the modified Bessel function and  $w = 2z\sqrt{z/3}$ .

function and  $w = 2z\sqrt{z/3}$ .

For very large  $|z|$ , argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller  $|z|$ , the computation is performed but results are accurate to less than half of machine precision. If  $\operatorname{Re} z$  is too large, and the unscaled function is required, there is a risk of

overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

#### 4. References

- [2] Hammersley J M and Handscomb D C (1967) Monte-Carlo Methods. Methuen.

#### 5. Parameters

- 1: DERIV -- CHARACTER\*1 Input  
 On entry: specifies whether the function or its derivative is required.  
     If DERIV = 'F', Bi(z) is returned.  
     If DERIV = 'D', Bi'(z) is returned.  
 Constraint: DERIV = 'F' or 'D'.
- 2: Z -- COMPLEX(KIND(1.0D0)) Input  
 On entry: the argument z of the function.
- 3: SCALE -- CHARACTER\*1 Input  
 On entry: the scaling option.  
     If SCALE = 'U', the result is returned unscaled.  
     If SCALE = 'S', the result is returned scaled by the  
     
$$\frac{|\operatorname{Re}(2z\sqrt{z/3})|}{\text{factor } e}$$
 Constraint: SCALE = 'U' or 'S'.
- 4: BI -- COMPLEX(KIND(1.0D0)) Output  
 On exit: the required function or derivative value.
- 5: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry DERIV /= 'F' or 'D'.

or SCALE /= 'U' or 'S'.

IFAIL= 2

No computation has been performed due to the likelihood of overflow, because real(Z) is too large - how large depends on the overflow threshold of the machine. This error exit can only occur when SCALE = 'U'.

IFAIL= 3

The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the result returned by S17DHF is accurate to less than half of machine precision. This error exit may occur if ABS(Z) is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 4

No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in the result returned by S17DHF would be lost. This error exit may occur if ABS(Z) is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 5

No result is returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S17DHF would have caused overflow or underflow.

#### 7. Accuracy

All constants in subroutine S17DHF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used  $t$ , then clearly the maximum number of correct digits in the results obtained is limited by  $p = \min(t, 18)$ . Because of errors in argument reduction when computing elementary functions inside S17DHF, the actual number of correct digits is limited, in general, by  $p - s$ , where  $s \sim \max(1, \log_{10} |z|)$  represents the number of digits lost due to

10

the argument reduction. Thus the larger the value of  $|z|$ , the less the precision in the result.

Empirical tests with modest values of  $z$ , checking relations between Airy functions  $Ai(z)$ ,  $Ai'(z)$ ,  $Bi(z)$  and  $Bi'(z)$ , have shown errors limited to the least significant 3-4 digits of precision.

8. Further Comments

Note that if the function is required to operate on a real argument only, then it may be much cheaper to call S17AHF or S17AKF.

9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the parameter DERIV, the second is a complex value for the argument,  $Z$ , and the third is a value for the parameter SCALE. The program calls the routine and prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S17 -- Approximations of Special Functions S17DLF  
 S17DLF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S17DLF returns a sequence of values for the Hankel functions  
 (1) (2)  
 $H_{(\nu)+n}(z)$  or  $H_{(\nu)+n}(z)$  for complex  $z$ , non-negative ( $\nu$ ) and  
 $n=0,1,\dots,N-1$ , with an option for exponential scaling.

2. Specification

```

SUBROUTINE S17DLF (M, FNU, Z, N, SCALE, CY, NZ, IFAIL)
INTEGER          M, N, NZ, IFAIL
DOUBLE PRECISION FNU
COMPLEX(KIND(1.0D0)) Z, CY(N)
    
```

CHARACTER\*1

SCALE

## 3. Description

This subroutine evaluates a sequence of values for the Hankel function  $H_{(\nu)}^{(1)}(z)$  or  $H_{(\nu)}^{(2)}(z)$ , where  $z$  is complex,  $-(\pi) < \arg z \leq (\pi)$ , and  $(\nu)$  is the real, non-negative order. The  $N$ -member sequence is generated for orders  $(\nu)$ ,  $(\nu)+1, \dots, (\nu)+N-1$ .

Optionally, the sequence is scaled by the factor  $e^{-iz}$  if the function is  $H_{(\nu)}^{(1)}(z)$  or by the factor  $e^{iz}$  if the function is  $H_{(\nu)}^{(2)}(z)$ .

$H_{(\nu)}^{(1)}(z)$ .  
 $H_{(\nu)}^{(2)}(z)$ .

Note: although the routine may not be called with  $(\nu)$  less than zero, for negative orders the formulae

$H_{(\nu)}^{(1)}(z) = e^{(\nu)(\pi)i} H_{(\nu)}^{(1)}(z)$ , and  $H_{(\nu)}^{(2)}(z) = e^{-(\nu)(\pi)i} H_{(\nu)}^{(2)}(z)$  may be used.

The routine is derived from the routine CBESH in Amos [2]. It is based on the relation

$$H_{(\nu)}^{(m)}(z) = -e^{\frac{1-p(\nu)}{p} K_{(\nu)}^{-p}(ze^{\frac{p}{2}})},$$

where  $p=i$  if  $m=1$  and  $p=-i$  if  $m=2$ , and the Bessel function  $K_{(\nu)}(z)$  is computed in the right half-plane only.

Continuation of  $K_{(\nu)}(z)$  to the left half-plane is computed in terms of the Bessel function  $I_{(\nu)}(z)$ . These functions are

evaluated using a variety of different techniques, depending on the region under consideration.

When  $N$  is greater than 1, extra values of  $H_{(\nu)}^{(m)}(z)$  are computed using recurrence relations.

factor  $e^{-iz}$  when  $M = 1$ , or by the factor  $e^{iz}$  when  $M = 2$ .  
 Constraint: SCALE = 'U' or 'S'.

6: CY(N) -- COMPLEX(KIND(1.0D)) array Output  
 On exit: the N required function values: CY(i) contains  
 (M)  
 $H$ , for  $i=1,2,\dots,N$ .  
 (nu)+i-1

7: NZ -- INTEGER Output  
 On exit: the number of components of CY that are set to zero  
 due to underflow. If  $NZ > 0$ , then if  $\text{Im}z > 0.0$  and  $M = 1$ , or  
 $\text{Im}z < 0.0$  and  $M = 2$ , elements CY(1), CY(2), ..., CY(NZ) are set  
 to zero. In the complementary half-planes, NZ simply states  
 the number of underflows, and not which elements they are.

8: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not  
 familiar with this parameter (described in the Essential  
 Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see  
 Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are  
 output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry  $M \neq 1$  and  $M \neq 2$ ,

or  $\text{FNU} < 0.0$ ,

or  $Z = (0.0, 0.0)$ ,

or  $N < 1$ ,

or SCALE  $\neq$  'U' or 'S'.

IFAIL= 2

No computation has been performed due to the likelihood of  
 overflow, because  $\text{ABS}(Z)$  is less than a machine-dependent  
 threshold value (given in the Users' Note for your  
 implementation).

## IFAIL= 3

No computation has been performed due to the likelihood of overflow, because  $FNU + N - 1$  is too large - how large depends on  $Z$  and the overflow threshold of the machine.

## IFAIL= 4

The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the results returned by S17DLF are accurate to less than half of machine precision. This error exit may occur if either  $ABS(Z)$  or  $FNU + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

## IFAIL= 5

No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by S17DLF would be lost. This error exit may occur when either of  $ABS(Z)$  or  $FNU + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

## IFAIL= 6

No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S17DLF would have caused overflow or underflow.

## 7. Accuracy

All constants in subroutine S17DLF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used  $t$ , then clearly the maximum number of correct digits in the results obtained is limited by  $p = \min(t, 18)$ . Because of errors in argument reduction when computing elementary functions inside S17DLF, the actual number of correct digits is limited, in general, by  $p - s$ , where  $s \sim \max(1, |\log |z||, |\log (nu)|)$  represents the number of digits

10                    10

lost due to the argument reduction. Thus the larger the values of  $|z|$  and  $(nu)$ , the less the precision in the result. If S17DLF is called with  $N > 1$ , then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S17DLF with different base values of  $(nu)$  and different  $N$ , the computed values may not agree exactly. Empirical tests with modest values of  $(nu)$  and  $z$  have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

## 8. Further Comments

The time taken by the routine for a call of S17DLF is approximately proportional to the value of  $N$ , plus a constant. In general it is much cheaper to call S17DLF with  $N$  greater than 1, rather than to make  $N$  separate calls to S17DLF.

Paradoxically, for some values of  $z$  and  $(nu)$ , it is cheaper to call S17DLF with a larger value of  $N$  than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different  $N$ , and the costs in each region may differ greatly.

## 9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the kind of function,  $M$ , the second is a value for the order  $FNU$ , the third is a complex value for the argument,  $Z$ , and the fourth is a value for the parameter  $SCALE$ . The program calls the routine with  $N = 2$  to evaluate the function for orders  $FNU$  and  $FNU + 1$ , and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S18 -- Approximations of Special Functions S18ACF  
 S18ACF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

S18ACF returns the value of the modified Bessel Function  $K(x)$ ,  
0  
 via the routine name.

## 2. Specification

DOUBLE PRECISION FUNCTION S18ACF (X, IFAIL)

INTEGER IFAIL  
 DOUBLE PRECISION X

3. Description

This routine evaluates an approximation to the modified Bessel Function of the second kind  $K_0(x)$ .

Note:  $K_0(x)$  is undefined for  $x \leq 0$  and the routine will fail for such arguments.

The routine is based on five Chebyshev expansions:

For  $0 < x \leq 1$ ,

$$K_0(x) = -\ln x \sum_{r=0}^{\infty} a_r T_r(t) + \sum_{r=0}^{\infty} b_r T_r(t), \text{ where } t = 2x - 1;$$

For  $1 < x \leq 2$ ,

$$K_0(x) = e^{-x} \sum_{r=0}^{\infty} c_r T_r(t), \text{ where } t = 2x - 3;$$

For  $2 < x \leq 4$ ,

$$K_0(x) = e^{-x} \sum_{r=0}^{\infty} d_r T_r(t), \text{ where } t = x - 3;$$

For  $x > 4$ ,

$$K_0(x) = \frac{e^{-x}}{\sqrt{x}} \sum_{r=0}^{\infty} e_r T_r(t), \text{ where } t = \frac{9-x}{1+x}.$$

For  $x$  near zero,  $K_0(x) \sim -(\gamma) - \ln(x)$ , where  $(\gamma)$  denotes Euler's constant.

This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision.

For large  $x$ , where there is a danger of underflow due to the smallness of  $K$ , the result is set exactly to zero.

0

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

1: X -- DOUBLE PRECISION Input  
 On entry: the argument  $x$  of the function. Constraint:  $X > 0$ .  
 0.

2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 $X \leq 0.0$ ,  $K$  is undefined. On soft failure the routine  
 0  
 returns zero.

#### 7. Accuracy

Let  $(\delta)$  and  $(\epsilon)$  be the relative errors in the argument and result respectively.

If  $(\delta)$  is somewhat larger than the machine precision (i.e., if  $(\delta)$  is due to data errors etc), then  $(\epsilon)$  and  $(\delta)$  are approximately related by:

$$(\epsilon) \sim \frac{|xK(x)|}{|K(x)|} (\delta).$$

Figure 1 shows the behaviour of the error amplification factor

$$|xK(x)|$$

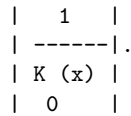

Figure 1

Please see figure in printed Reference Manual

However, if  $(\delta)$  is of the same order as machine precision, then rounding errors could make  $(\epsilon)$  slightly larger than the above relation predicts.

For small  $x$ , the amplification factor is approximately  $\frac{1}{|\ln x|}$ , which implies strong attenuation of the error, but in general  $(\epsilon)$  can never be less than the machine precision.

For large  $x$ ,  $(\epsilon) \sim x(\delta)$  and we have strong amplification of the relative error. Eventually  $K$ , which is asymptotically

$e^{-x}$   
 given by  $\frac{1}{e^x}$ , becomes so small that it cannot be calculated

$\sqrt{x}$   
 without underflow and hence the routine will return zero. Note that for large  $x$  the errors will be dominated by those of the Fortran intrinsic function EXP.

8. Further Comments

For details of the time taken by the routine see the appropriate the Users' Note for your implementation.

9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S18ADF returns the value of the modified Bessel Function  $K(x)$ ,  
 1  
 via the routine name.

### 2. Specification

```
DOUBLE PRECISION FUNCTION S18ADF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

### 3. Description

This routine evaluates an approximation to the modified Bessel Function of the second kind  $K(x)$ .

1

Note:  $K(x)$  is undefined for  $x \leq 0$  and the routine will fail for  
 1  
 such arguments.

The routine is based on five Chebyshev expansions:

For  $0 < x \leq 1$ ,

$$K(x) = \frac{1}{x} \ln x + \sum_{r=0}^1 a_r T_r(t) - x \sum_{r=0}^2 b_r T_r(t), \text{ where } t = 2x - 1;$$

For  $1 < x \leq 2$ ,

$$K(x) = e^{-x} \sum_{r=0}^1 c_r T_r(t), \text{ where } t = 2x - 3;$$

For  $2 < x \leq 4$ ,

$$K(x) = e^{-x} \sum_{r=0}^1 d_r T_r(t), \text{ where } t = x - 3;$$

For  $x > 4$ ,

$$K(x) = \frac{e^{-x}}{\sqrt{x}} \int_0^1 e^{-rt} T(t) dt, \text{ where } t = \frac{9-x}{1+x}$$

For  $x$  near zero,  $K(x) \sim \frac{1}{x}$ . This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision. For very small  $x$  on some machines, it is impossible to calculate  $\frac{1}{x}$  without overflow and the routine must fail.

For large  $x$ , where there is a danger of underflow due to the smallness of  $K$ , the result is set exactly to zero.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

- 1: X -- DOUBLE PRECISION Input  
 On entry: the argument  $x$  of the function. Constraint:  $X > 0$ .  
 0.
- 2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 $X \leq 0.0$ ,  $K$  is undefined. On soft failure the routine returns zero.

IFAIL= 2

X is too small, there is a danger of overflow. On soft failure the routine returns approximately the largest representable value.

### 7. Accuracy

Let  $(\delta)$  and  $(\epsilon)$  be the relative errors in the argument and result respectively.

If  $(\delta)$  is somewhat larger than the machine precision (i.e., if  $(\delta)$  is due to data errors etc), then  $(\epsilon)$  and  $(\delta)$  are approximately related by:

$$(\epsilon) \sim \left| \frac{xK(x) - K(x)}{K(x)} \right| (\delta).$$

Figure 1 shows the behaviour of the error amplification factor

$$\left| \frac{xK(x) - K(x)}{K(x)} \right|.$$

Figure 1

Please see figure in printed Reference Manual

However if  $(\delta)$  is of the same order as the machine precision, then rounding errors could make  $(\epsilon)$  slightly larger than the above relation predicts.

For small  $x$ ,  $(\epsilon) \sim (\delta)$  and there is no amplification of errors.

For large  $x$ ,  $(\epsilon) \sim x(\delta)$  and we have strong amplification of the relative error. Eventually  $K$ , which is asymptotically

1

$e^{-x}$

given by  $e^{-x}$ , becomes so small that it cannot be calculated

$\sqrt{x}$

without underflow and hence the routine will return zero. Note that for large  $x$  the errors will be dominated by those of the Fortran intrinsic function EXP.

8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S18 -- Approximations of Special Functions S18AEF  
 S18AEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S18AEF returns the value of the modified Bessel Function  $I_0(x)$ ,  
0  
 via the routine name.

2. Specification

```

    DOUBLE PRECISION FUNCTION S18AEF (X, IFAIL)
    INTEGER          IFAIL
    DOUBLE PRECISION X
    
```

3. Description

This routine evaluates an approximation to the modified Bessel Function of the first kind  $I_0(x)$ .  
0

Note:  $I_0(-x) = I_0(x)$ , so the approximation need only consider  $x \geq 0$ .  
0      0

The routine is based on three Chebyshev expansions:

For  $0 < x \leq 4$ ,

$$x \rightarrow I_0(x)$$

$$I_0(x) = e^{-x} \int_0^x a T(t) dt, \text{ where } t = 2(x-t)^{-1}; \quad (4)$$

For  $4 < x \leq 12$ ,

$$I_0(x) = e^{-x} \int_0^x b T(t) dt, \text{ where } t = \frac{x-8}{4};$$

For  $x > 12$ ,

$$I_0(x) = \frac{e^{-x}}{\sqrt{x}} \int_0^x c T(t) dt, \text{ where } t = 2\left(\frac{x}{t}\right)^{-1}. \quad (12)$$

For small  $x$ ,  $I_0(x) \sim 1$ . This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision.

For large  $x$ , the routine must fail because of the danger of overflow in calculating  $e^{-x}$ .

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

1: X -- DOUBLE PRECISION Input  
On entry: the argument  $x$  of the function.

2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

X is too large. On soft failure the routine returns the approximate value of I (x) at the nearest valid argument.

0

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e., if (delta) is due to data errors etc), then (epsilon) and (delta) are approximately related by:

$$(\text{epsilon}) \sim \left| \frac{x I(x)}{I(x)} \right| (\text{delta})$$

Figure 1 shows the behaviour of the error amplification factor

$$\left| \frac{x I(x)}{I(x)} \right|$$

Figure 1

Please see figure in printed Reference Manual

However if (delta) is of the same order as machine precision, then rounding errors could make (epsilon) slightly larger than the above relation predicts.

For small x the amplification factor is approximately  $\frac{x^2}{2}$ , which implies strong attenuation of the error, but in general (epsilon) can never be less than the machine precision.

For large x,  $(\text{epsilon}) \sim x(\text{delta})$  and we have strong amplification of errors. However the routine must fail for quite moderate values of x, because I (x) would overflow; hence in practice the

0

loss of accuracy for large x is not excessive. Note that for large x the errors will be dominated by those of the Fortran intrinsic function EXP.

## 8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

## 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

```

```
S18 -- Approximations of Special Functions          S18AFF
S18AFF -- NAG Foundation Library Routine Document
```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

S18AFF returns a value for the modified Bessel Function  $I_1(x)$ ,  
via the routine name.

## 2. Specification

```
DOUBLE PRECISION FUNCTION S18AFF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

## 3. Description

This routine evaluates an approximation to the modified Bessel Function of the first kind  $I_1(x)$ .  
1

Note:  $I_1(-x) = -I_1(x)$ , so the approximation need only consider  $x \geq 0$   
1 1

The routine is based on three Chebyshev expansions:

For  $0 < x \leq 4$ ,

```
--' ( x)2
```

$$I_1(x) = x^{-1} \int_0^x a T(t) dt, \text{ where } t = 2(x^{-1})^{-1}; \quad (4)$$

r=0

For  $4 < x \leq 12$ ,

$$I_1(x) = e^{-x} \int_0^x b T(t) dt, \text{ where } t = \frac{x-8}{4};$$

r=0

For  $x > 12$ ,

$$I_1(x) = \frac{e^{-x}}{\sqrt{x}} \int_0^x c T(t) dt, \text{ where } t = 2\left(\frac{x}{\sqrt{x}}\right)^{-1}. \quad (12)$$

r=0

For small  $x$ ,  $I_1(x) \sim x$ . This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision.

For large  $x$ , the routine must fail because  $I_1(x)$  cannot be represented without overflow.

4. References

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S18 -- Approximations of Special Functions S18DCF  
 S18DCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S18DCF returns a sequence of values for the modified Bessel functions  $K_{\nu}(z)$  for complex  $z$ , non-negative ( $\nu$ ) and  $(\nu)+n$   $n=0,1,\dots,N-1$ , with an option for exponential scaling.

2. Specification

```

SUBROUTINE S18DCF (FNU, Z, N, SCALE, CY, NZ, IFAIL)
INTEGER          N, NZ, IFAIL
DOUBLE PRECISION FNU
COMPLEX(KIND(1.0D0)) Z, CY(N)
CHARACTER*1     SCALE
    
```

3. Description

This subroutine evaluates a sequence of values for the modified Bessel function  $K_{\nu}(z)$ , where  $z$  is complex,  $-(\pi) < \arg z \leq (\pi)$ , and  $(\nu)$  is the real, non-negative order. The  $N$ -member sequence is generated for orders  $(\nu)$ ,  $(\nu)+1, \dots, (\nu)+N-1$ .

Optionally, the sequence is scaled by the factor  $e^{-z}$ .

The routine is derived from the routine CBESK in Amos [2].

Note: although the routine may not be called with  $(\nu)$  less than zero, for negative orders the formula  $K_{-\nu}(z) = K_{\nu}(z)$  may be used.

used.

When  $N$  is greater than 1, extra values of  $K_{(\nu)}(z)$  are computed using recurrence relations.

For very large  $|z|$  or  $((\nu)+N-1)$ , argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller  $|z|$  or  $((\nu)+N-1)$ , the computation is performed but results are accurate to less than half of machine precision. If  $|z|$  is very small, near the machine underflow threshold, or  $((\nu)+N-1)$  is too large, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.
- [2] Amos D E (1986) Algorithm 644: A Portable Package for Bessel Functions of a Complex Argument and Nonnegative Order. ACM Trans. Math. Softw. 12 265--273.

#### 5. Parameters

- 1: FNU -- DOUBLE PRECISION Input  
On entry: the order,  $(\nu)$ , of the first member of the sequence of functions. Constraint: FNU  $\geq$  0.0.
- 2: Z -- COMPLEX(KIND(1.0D0)) Input  
On entry: the argument  $z$  of the functions. Constraint: Z  $\neq$  (0.0, 0.0).
- 3: N -- INTEGER Input  
On entry: the number,  $N$ , of members required in the sequence  $K_{(\nu)}(z), K_{(\nu)+1}(z), \dots, K_{(\nu)+N-1}(z)$ . Constraint:  $N \geq 1$ .
- 4: SCALE -- CHARACTER\*1 Input  
On entry: the scaling option.  
  
If SCALE = 'U', the results are returned unscaled.  
  
If SCALE = 'S', the results are returned scaled by the factor  $e^{-z}$ . Constraint: SCALE = 'U' or 'S'.
- 5: CY(N) -- COMPLEX(KIND(1.0D)) array Output  
On exit: the  $N$  required function values: CY(i) contains

either  $\text{ABS}(Z)$  or  $\text{FNU} + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 5

No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by S18DCF would be lost. This error exit may occur when either  $\text{ABS}(Z)$  or  $\text{FNU} + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 6

No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S18DCF would have caused overflow or underflow.

## 7. Accuracy

All constants in subroutine S18DCF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used  $t$ , then clearly the maximum number of correct digits in the results obtained is limited by  $p = \min(t, 18)$ . Because of errors in argument reduction when computing elementary functions inside S18DCF, the actual number of correct digits is limited, in general, by  $p - s$ , where  $s = \max(1, \log_{10} |z|, \log_{10} (\text{nu}))$  represents the number of digits

lost due to the argument reduction. Thus the larger the values of  $|z|$  and  $(\text{nu})$ , the less the precision in the result. If S18DCF is called with  $N > 1$ , then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S18DCF with different base values of  $(\text{nu})$  and different  $N$ , the computed values may not agree exactly. Empirical tests with modest values of  $(\text{nu})$  and  $z$  have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

## 8. Further Comments

The time taken by the routine for a call of S18DCF is approximately proportional to the value of  $N$ , plus a constant. In general it is much cheaper to call S18DCF with  $N$  greater than 1, rather than to make  $N$  separate calls to S18DCF.

Paradoxically, for some values of  $z$  and  $(\text{nu})$ , it is cheaper to

call S18DCF with a larger value of N than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different N, and the costs in each region may differ greatly.

Note that if the function required is  $K_0(x)$  or  $K_1(x)$ , i.e.,  
 $(\text{nu})=0.0$  or  $1.0$ , where  $x$  is real and positive, and only a single function value is required, then it may be much cheaper to call S18ACF, S18ADF, S18CCF(\*) or S18CDF(\*), depending on whether a scaled result is required or not.

9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the order FNU, the second is a complex value for the argument, Z, and the third is a value for the parameter SCALE. The program calls the routine with  $N = 2$  to evaluate the function for orders FNU and FNU + 1, and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S18 -- Approximations of Special Functions S18DEF  
 S18DEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S18DEF returns a sequence of values for the modified Bessel functions  $I_{\nu+n}(z)$  for complex  $z$ , non-negative  $(\text{nu})$  and  $n=0,1,\dots,N-1$ , with an option for exponential scaling.

2. Specification

SUBROUTINE S18DEF (FNU, Z, N, SCALE, CY, NZ, IFAIL)  
 INTEGER N, NZ, IFAIL

```

DOUBLE PRECISION      FNU
COMPLEX(KIND(1.0D0)) Z, CY(N)
CHARACTER*1           SCALE

```

### 3. Description

This subroutine evaluates a sequence of values for the modified Bessel function  $I_{\nu}(z)$ , where  $z$  is complex,  $-(\pi) < \arg z \leq$

$(\pi)$ , and  $(\nu)$  is the real, non-negative order. The  $N$ -member sequence is generated for orders  $(\nu)$ ,  $(\nu)+1, \dots, (\nu)+N-1$ .

Optionally, the sequence is scaled by the factor  $e^{-|\operatorname{Re}z|}$ .

The routine is derived from the routine CBESI in Amos [2].

Note: although the routine may not be called with  $(\nu)$  less than zero, for negative orders the formula

$$I_{-\nu}(z) = I_{\nu}(z) + \frac{\sin((\pi)(\nu))}{\pi} K_{\nu}(z)$$

may be used (for the Bessel function  $K_{\nu}(z)$ , see S18DCF).

When  $N$  is greater than 1, extra values of  $I_{\nu}(z)$  are computed using recurrence relations.

For very large  $|z|$  or  $((\nu)+N-1)$ , argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller  $|z|$  or  $((\nu)+N-1)$ , the computation is performed but results are accurate to less than half of machine precision. If  $\operatorname{Re}(z)$  is too large and the unscaled function is required, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

### 4. References

- [2] Amos D E (1986) Algorithm 644: A Portable Package for Bessel Functions of a Complex Argument and Nonnegative Order. ACM Trans. Math. Softw. 12 265--273.

### 5. Parameters

1: FNU -- DOUBLE PRECISION Input  
 On entry: the order,  $(\nu)$ , of the first member of the sequence of functions. Constraint: FNU  $\geq$  0.0.

- 2: Z -- COMPLEX(KIND(1.0D0)) Input  
 On entry: the argument z of the functions.
- 3: N -- INTEGER Input  
 On entry: the number, N, of members required in the sequence  
 $I_{(z)}$ ,  $I_{(z)}$ , ...,  $I_{(z)}$ . Constraint:  $N \geq 1$ .  
 $(nu)$   $(nu)+1$   $(nu)+N-1$
- 4: SCALE -- CHARACTER\*1 Input  
 On entry: the scaling option.  
 If SCALE = 'U', the results are returned unscaled.  
  
 If SCALE = 'S', the results are returned scaled by the  
 $-|Re z|$   
 factor  $e$  .  
 Constraint: SCALE = 'U' or 'S'.
- 5: CY(N) -- COMPLEX(KIND(1.0D)) array Output  
 On exit: the N required function values: CY(i) contains  
 $I_{(z)}$ , for  $i=1,2,\dots,N$ .  
 $(nu)+i-1$
- 6: NZ -- INTEGER Output  
 On exit: the number of components of CY that are set to zero  
 due to underflow.  
  
 If  $NZ > 0$ , then elements  $CY(N-NZ+1), CY(N-NZ+2), \dots, CY(N)$  are  
 set to zero.
- 7: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not  
 familiar with this parameter (described in the Essential  
 Introduction) the recommended value is 0.  
  
 On exit: IFAIL = 0 unless the routine detects an error (see  
 Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are  
 output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry  $FNU < 0.0$ ,

or  $N < 1$ ,

or SCALE /= 'U' or 'S'.

IFAIL= 2

No computation has been performed due to the likelihood of overflow, because  $\text{real}(Z)$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation). This error exit can only occur when SCALE = 'U'.

IFAIL= 3

The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the results returned by S18DEF are accurate to less than half of machine precision. This error exit may occur when either  $\text{ABS}(Z)$  or  $\text{FNU} + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 4

No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by S18DEF would be lost. This error exit may occur when either  $\text{ABS}(Z)$  or  $\text{FNU} + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 5

No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S18DEF would have caused overflow or underflow.

## 7. Accuracy

All constants in subroutine S18DEF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used  $t$ , then clearly the maximum number of correct digits in the results obtained is limited by  $p = \min(t, 18)$ . Because of errors in argument reduction when computing elementary functions inside S18DEF, the actual number of correct digits is limited, in general, by  $p - s$ , where  $s = \max(1, \log_{10} |z|, \log_{10} (\text{nu}))$  represents the number of digits

lost due to the argument reduction. Thus the larger the values of  $|z|$  and  $(\text{nu})$ , the less the precision in the result. If S18DEF is called with  $N > 1$ , then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S18DEF with different base values of  $(\text{nu})$

and different N, the computed values may not agree exactly. Empirical tests with modest values of (nu) and z have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

8. Further Comments

The time taken by the routine for a call of S18DEF is approximately proportional to the value of N, plus a constant. In general it is much cheaper to call S18DEF with N greater than 1, rather than to make N separate calls to S18DEF.

Paradoxically, for some values of z and (nu), it is cheaper to call S18DEF with a larger value of N than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different N, and the costs in each region may differ greatly.

Note that if the function required is  $I_0(x)$  or  $I_1(x)$ , i.e., (nu)=0.0 or 1.0, where x is real and positive, and only a single function value is required, then it may be much cheaper to call S18AEF, S18AFF, S18CEF(\*) or S18CFF(\*), depending on whether a scaled result is required or not.

9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the order FNU, the second is a complex value for the argument, Z, and the third is a value for the parameter SCALE. The program calls the routine with N = 2 to evaluate the function for orders FNU and FNU + 1, and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S19 -- Approximations of Special Functions S19AAF  
 S19AAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is

not included in the Foundation Library.

### 1. Purpose

S19AAF returns a value for the Kelvin function ber x via the routine name.

### 2. Specification

```
DOUBLE PRECISION FUNCTION S19AAF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

### 3. Description

This routine evaluates an approximation to the Kelvin function berx.

Note: ber(-x)=berx, so the approximation need only consider x>=0.0.

The routine is based on several Chebyshev expansions:

For  $0 \leq x \leq 5$ ,

$$\text{berx} = \sum_{r=0}^{\infty} a_r T_r(t) \quad \text{with } t = 2\left(\frac{x}{5}\right) - 1;$$

For  $x > 5$ ,

$$\text{berx} = \frac{e^{x/\sqrt{2}}}{\sqrt{2(\pi)x}} \left[ \frac{[(1 - a(t))\cos(\alpha) + b(t)\sin(\alpha)]}{x} \right]$$

$$+ \frac{e^{-x/\sqrt{2}}}{\sqrt{2(\pi)x}} \left[ \frac{[(1 - c(t))\sin(\beta) + d(t)\cos(\beta)]}{x} \right]$$

where  $(\alpha) = \frac{x}{\sqrt{2}} - \frac{(\pi)}{2}$ ,  $(\beta) = \frac{x}{\sqrt{2}} + \frac{(\pi)}{2}$ ,

$$\sqrt[8]{2} \quad /2$$

and  $a(t)$ ,  $b(t)$ ,  $c(t)$ , and  $d(t)$  are expansions in the variable  
 $t = \frac{10}{x} - 1$ .

When  $x$  is sufficiently close to zero, the result is set directly to  $ber\ 0=1.0$ .

For large  $x$ , there is a danger of the result being totally inaccurate, as the error amplification factor grows in an essentially exponential manner; therefore the routine must fail.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input  
 On entry: the argument  $x$  of the function.

2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 On entry ABS(X) is too large for an accurate result to be returned. On soft failure, the routine returns zero.

7. Accuracy

Since the function is oscillatory, the absolute error rather than the relative error is important. Let  $E$  be the absolute error in the result and  $(\delta)$  be the relative error in the argument. If  $(\delta)$  is somewhat larger than the machine precision, then we have:

$$|x|$$

$$E^* = \frac{1}{\sqrt{2}} \left| \frac{1}{\sqrt{2}} (\operatorname{ber} x + \operatorname{bei} x) \right| (\delta)$$

(provided  $E$  is within machine bounds).

For small  $x$  the error amplification is insignificant and thus the absolute error is effectively bounded by the machine precision.

For medium and large  $x$ , the error behaviour is oscillatory and

its amplitude grows like  $\frac{x}{\sqrt{2\pi}}$ . Therefore it is not

possible to calculate the function with any accuracy when

$\frac{x}{\sqrt{2\pi}} > \frac{1}{\delta}$ . Note that this value of  $x$  is much smaller than

the minimum value of  $x$  for which the function overflows.

#### 8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

#### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S19 -- Approximations of Special Functions S19ABF  
S19ABF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S19ABF returns a value for the Kelvin function  $\text{bei } x$  via the routine name.

2. Specification

DOUBLE PRECISION FUNCTION S19ABF (X, IFAIL)  
 INTEGER IFAIL  
 DOUBLE PRECISION X

3. Description

This routine evaluates an approximation to the Kelvin function  $\text{beix}$ .

Note:  $\text{bei}(-x)=\text{beix}$ , so the approximation need only consider  $x \geq 0.0$ .

The routine is based on several Chebyshev expansions:

For  $0 \leq x \leq 5$ ,

$$\text{bei } x = \sum_{r=0}^2 \frac{x^{2r}}{4^{r+1}} a_r T_r(t), \quad \text{with } t = 2\left(\frac{x}{5}\right)^4 - 1;$$

For  $x > 5$ ,

$$\text{bei } x = \frac{e^{x/\sqrt{2}}}{\sqrt{2(\pi)x}} \left[ \frac{[(1 + \frac{1}{x}) \sin(\alpha) - \frac{1}{x} \cos(\alpha)]}{[(1 + \frac{1}{x}) \sin(\alpha) - \frac{1}{x} \cos(\alpha)]} \right]$$

$$+ \frac{e^{x/\sqrt{2}}}{\sqrt{2(\pi)x}} \left[ \frac{[(1 - \frac{1}{x}) \cos(\beta) - \frac{1}{x} \sin(\beta)]}{[(1 - \frac{1}{x}) \cos(\beta) - \frac{1}{x} \sin(\beta)]} \right]$$

where  $\alpha = \frac{x}{\sqrt{2}} \frac{(\pi)}{8}$ ,  $(\beta) = \frac{x}{\sqrt{2}} \frac{(\pi)}{8} + \frac{(\pi)}{8}$ ,

and  $a(t)$ ,  $b(t)$ ,  $c(t)$ , and  $d(t)$  are expansions in the variable  
 $10$   
 $t = \dots - 1.$   
 $x$

When  $x$  is sufficiently close to zero, the result is computed as  
 $2$   
 $x$   
 bei  $x = \dots$ . If this result would underflow, the result returned is  
 $4$   
 beix=0.0.

For large  $x$ , there is a danger of the result being totally inaccurate, as the error amplification factor grows in an essentially exponential manner; therefore the routine must fail.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
 On entry: the argument  $x$  of the function.
- 2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 On entry ABS(X) is too large for an accurate result to be returned. On soft failure, the routine returns zero.

#### 7. Accuracy

Since the function is oscillatory, the absolute error rather than the relative error is important. Let  $E$  be the absolute error in the function, and  $(\delta)$  be the relative error in the argument. If  $(\delta)$  is somewhat larger than the machine precision, then we have:

$$E \sim \left| \frac{x}{\sqrt{2}} \frac{(-\text{ber } x + \text{bei } x)}{1} \right| (\text{delta})$$

(provided E is within machine bounds).

For small x the error amplification is insignificant and thus the absolute error is effectively bounded by the machine precision.

For medium and large x, the error behaviour is oscillatory and

its amplitude grows like  $\frac{1}{\sqrt{2(\pi)}} e^{x/\sqrt{2}}$ . Therefore it is

impossible to calculate the functions with any accuracy when

$\frac{x/\sqrt{2}}{\sqrt{2(\pi)}} > \frac{1}{\text{delta}}$ . Note that this value of x is much smaller than (delta)

the minimum value of x for which the function overflows.

8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S19 -- Approximations of Special Functions S19ACF  
 S19ACF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

S19ACF returns a value for the Kelvin function  $\ker x$ , via the routine name.

## 2. Specification

```
DOUBLE PRECISION FUNCTION S19ACF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

## 3. Description

This routine evaluates an approximation to the Kelvin function  $\ker x$ .

Note: for  $x < 0$  the function is undefined and at  $x = 0$  it is infinite so we need only consider  $x > 0$ .

The routine is based on several Chebyshev expansions:

For  $0 < x \leq 1$ ,

$$\ker x = -f(t) \log x + \frac{(\pi)^2}{16} x g(t) + y(t)$$

where  $f(t)$ ,  $g(t)$  and  $y(t)$  are expansions in the variable  $t = 2x^4 - 1$ ;

For  $1 < x \leq 3$ ,

$$\ker x = \exp\left(-\frac{x}{16}\right) q(t)$$

where  $q(t)$  is an expansion in the variable  $t = x - 2$ ;

For  $x > 3$ ,

$$\ker x = \frac{(\pi)^{-x/\sqrt{2}}}{\sqrt{2x}} \frac{[(1 - c(t)) \cos(\beta) - d(t) \sin(\beta)]}{[(x) \quad x]}$$

$$x \quad (\pi)$$

where  $(\beta) = \frac{1}{8} + \frac{\sqrt{2}}{8}$ , and  $c(t)$  and  $d(t)$  are expansions in the

variable  $t = \frac{\sqrt{2}}{x}$ .

When  $x$  is sufficiently close to zero, the result is computed as

$$\ker x = -(\gamma) - \log\left(\frac{x}{2}\right) + \left(\frac{\pi}{8}\right) - \frac{x^2}{16} + \dots$$

and when  $x$  is even closer to zero, simply as

$$\ker x = -(\gamma) - \log\left(\frac{x}{2}\right) + \dots$$

For large  $x$ ,  $\ker x$  is asymptotically given by  $\frac{(\pi)}{2x} e^{-x/\sqrt{2}}$  and

this becomes so small that it cannot be computed without underflow and the routine fails.

#### 4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
On entry: the argument  $x$  of the function. Constraint:  $X > 0$ .
- 2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

On entry X is too large, the result underflows. On soft failure, the routine returns zero.

IFAIL= 2

On entry X <= 0, the function is undefined. On soft failure the routine returns zero.

### 7. Accuracy

Let E be the absolute error in the result, (epsilon) be the relative error in the result and (delta) be the relative error in the argument. If (delta) is somewhat larger than the machine precision, then we have:

$$E \sim \left| \frac{x}{\sqrt{2}} \frac{\operatorname{ker} x + \operatorname{kei} x}{1} \right| (\delta),$$

$$(\epsilon) \sim \left| \frac{\operatorname{ker} x + \operatorname{kei} x}{x \sqrt{2}} \right| (\delta).$$

For very small x, the relative error amplification factor is approximately given by  $\frac{1}{|\log x|}$ , which implies a strong attenuation of relative error. However, (epsilon) in general cannot be less than the machine precision.

For small x, errors are damped by the function and hence are limited by the machine precision.

For medium and large x, the error behaviour, like the function itself, is oscillatory, and hence only the absolute accuracy for the function can be maintained. For this range of x, the

amplitude of the absolute error decays like  $\frac{1}{\sqrt{2}} \frac{(\pi)x^{-x/\sqrt{2}}}{e}$

which implies a strong attenuation of error. Eventually,  $\operatorname{ker} x$ ,

which asymptotically behaves like  $\frac{1}{\sqrt{2}} \frac{(\pi)^{-x/\sqrt{2}}}{e}$ , becomes so

$$\sqrt{2x}$$

small that it cannot be calculated without causing underflow, and the routine returns zero. Note that for large x the errors are dominated by those of the Fortran intrinsic function EXP.

8. Further Comments

Underflow may occur for a few values of x close to the zeros of ker x, below the limit which causes a failure with IFAIL = 1.

9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S19 -- Approximations of Special Functions S19ADF  
 S19ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S19ADF returns a value for the Kelvin function keix via the routine name.

2. Specification

```
DOUBLE PRECISION FUNCTION S19ADF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Kelvin function keix.

Note: for x<0 the function is undefined, so we need only consider x>=0.

The routine is based on several Chebyshev expansions:

For  $0 < x \leq 1$ ,

$$keix = -\frac{(\pi)^2}{4} f(t) + \frac{1}{4} [-g(t) \log x + v(t)]$$

where  $f(t)$ ,  $g(t)$  and  $v(t)$  are expansions in the variable  $t = 2x^{-1}$ ;

For  $1 < x \leq 3$ ,

$$keix = \exp(-x) u(t)$$

where  $u(t)$  is an expansion in the variable  $t = x^{-2}$ ;

For  $x > 3$ ,

$$keix = \frac{1}{\sqrt{2x}} \frac{(\pi)^{-x/\sqrt{2}} [(1-x)c(t)\sin(\beta) + d(t)\cos(\beta)]}{[(1-x)c(t)\sin(\beta) + d(t)\cos(\beta)]}$$

where  $(\beta) = \frac{x}{8} + \frac{(\pi)}{8}$ , and  $c(t)$  and  $d(t)$  are expansions in the

variable  $t = \frac{\sqrt{2}}{x^6} - 1$ .

For  $x < 0$ , the function is undefined, and hence the routine fails and returns zero.

When  $x$  is sufficiently close to zero, the result is computed as

$$keix = -\frac{(\pi)^2}{4} (1 - \gamma) - \log(2) - \frac{(\pi)^2}{4}$$

and when  $x$  is even closer to zero simply as

$$keix = -\frac{(\pi)^2}{4}$$

For large  $x$ ,  $keix$  is asymptotically given by  $\frac{1}{\sqrt{2x}} e^{-(\pi/2)x}$  and

this becomes so small that it cannot be computed without underflow and the routine fails.

4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

- 1: X -- DOUBLE PRECISION Input  
 On entry: the argument  $x$  of the function. Constraint:  $X \geq 0$ .
- 2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 On entry  $X$  is too large, the result underflows. On soft failure, the routine returns zero.

IFAIL= 2  
 On entry  $X < 0$ , the function is undefined. On soft failure the routine returns zero.

7. Accuracy

Let  $E$  be the absolute error in the result, and  $(\delta)$  be the relative error in the argument. If  $(\delta)$  is somewhat larger than the machine representation error, then we have:

$$E \approx \frac{x}{\sqrt{2x}} e^{-(\pi/2)x} (\delta)$$

$$\frac{1}{\sqrt{2}}$$

For small  $x$ , errors are attenuated by the function and hence are limited by the machine precision.

For medium and large  $x$ , the error behaviour, like the function itself, is oscillatory and hence only absolute accuracy of the function can be maintained. For this range of  $x$ , the amplitude of

the absolute error decays like  $\frac{1}{\sqrt{2}} \frac{e^{-(\pi)x}}{2}$ , which implies a

strong attenuation of error. Eventually,  $\text{keix}$ , which is

asymptotically given by  $\frac{1}{\sqrt{2x}} e^{-(\pi)x}$ , becomes so small that it

cannot be calculated without causing underflow and therefore the routine returns zero. Note that for large  $x$ , the errors are dominated by those of the Fortran intrinsic function EXP.

#### 8. Further Comments

Underflow may occur for a few values of  $x$  close to the zeros of  $\text{keix}$ , below the limit which causes a failure with  $\text{IFAIL} = 1$ .

#### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S20 -- Approximations of Special Functions S20ACF  
 S20ACF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S20ACF returns a value for the Fresnel Integral S(x), via the routine name.

2. Specification

```
DOUBLE PRECISION FUNCTION S20ACF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Fresnel Integral

$$S(x) = \int_0^x \frac{\sin\left(\frac{\pi}{2} t^2\right) dt}{\sqrt{2}}$$

Note: S(x)=-S(-x), so the approximation need only consider x>=0.0

The routine is based on three Chebyshev expansions:

For 0<x<=3,

$$S(x) = x \int_0^3 a_r T^r(t) dt, \text{ with } t = 2\left(\frac{x}{3}\right)^4 - 1;$$

For x>3,

$$S(x) = \frac{1}{2} \frac{f(x)}{x} \cos\left(\frac{\pi}{2} x\right) - \frac{g(x)}{3x} \sin\left(\frac{\pi}{2} x\right),$$

where  $f(x) = \int_0^3 b_r T^r(t) dt,$

and  $g(x) = \int_0^3 c_r T^r(t) dt, \text{ with } t = 2\left(\frac{x}{3}\right)^4 - 1.$

(pi) 3

For small  $x$ ,  $S(x) \sim \frac{1}{6}x^6$ . This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision. For very small  $x$ , this approximation would underflow; the result is then set exactly to zero.

For large  $x$ ,  $f(x) \sim \frac{1}{(\pi)^2}$  and  $g(x) \sim \frac{1}{2(\pi)^2}$ . Therefore for moderately large  $x$ , when  $\frac{1}{2^3(\pi)^3 x^3}$  is negligible compared with  $\frac{1}{2^2(\pi)^2}$ , the second term in the approximation for  $x > 3$  may be dropped. For very large  $x$ , when  $\frac{1}{(\pi)x}$  becomes negligible,  $S(x) \sim \frac{1}{2}$ . However there will be considerable difficulties in calculating  $\cos\left(\frac{(\pi)^2}{2}x\right)$  accurately before this final limiting value can be used. Since  $\cos\left(\frac{(\pi)^2}{2}x\right)$  is periodic, its value is essentially determined by the fractional part of  $x$ . If  $x = N + (\theta)$  where  $N$  is an integer and  $0 \leq (\theta) < 1$ , then  $\cos\left(\frac{(\pi)^2}{2}x\right)$  depends on  $(\theta)$  and on  $N$  modulo 4. By exploiting this fact, it is possible to retain significance in the calculation of  $\cos\left(\frac{(\pi)^2}{2}x\right)$  either all the way to the very large  $x$  limit, or at least until the integer part of  $\frac{x}{2}$  is equal to the maximum integer allowed on the machine.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

1: X -- DOUBLE PRECISION Input  
 On entry: the argument  $x$  of the function.

2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL has been included for consistency with other routines in this chapter.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e., if (delta) is due to data errors etc), then (epsilon) and (delta) are approximately related by:

$$(\epsilon) \sim \frac{(\pi)^2 |x \sin(\frac{x}{2})|}{S(x)} (\delta).$$

Figure 1 shows the behaviour of the error amplification factor

$$\frac{(\pi)^2 |x \sin(\frac{x}{2})|}{S(x)}$$

Figure 1  
 Please see figure in printed Reference Manual

However if (delta) is of the same order as the machine precision, then rounding errors could make (epsilon) slightly larger than the above relation predicts.

For small x, (epsilon)~3(delta) and hence there is only moderate amplification of relative error. Of course for very small x where the correct result would underflow and exact zero is returned, relative error-control is lost.

For moderately large values of  $x$ ,

$$|(\epsilon)| \sim \frac{(\pi/2)}{2x \sin(\frac{\pi}{2x})} |\delta|$$

and the result will be subject to increasingly large amplification of errors. However the above relation breaks down

for large values of  $x$  (i.e., when  $\frac{1}{2x}$  is of the order of the

machine precision in this region the relative error in the result

is essentially bounded by  $\frac{1}{(\pi)x}$ ).

Hence the effects of error amplification are limited and at worst the relative error loss should not exceed half the possible number of significant figures.

#### 8. Further Comments

None.

#### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S20 -- Approximations of Special Functions S20ADF  
 S20ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S20ADF returns a value for the Fresnel Integral  $C(x)$ , via the routine name.

#### 2. Specification

DOUBLE PRECISION FUNCTION S20ADF (X, IFAIL)  
 INTEGER IFAIL  
 DOUBLE PRECISION X

3. Description

This routine evaluates an approximation to the Fresnel Integral

$$C(x) = \int_0^x \frac{\cos\left(\frac{\pi}{2} t^2\right) dt}{\sqrt{2}}$$

Note:  $C(x) = -C(-x)$ , so the approximation need only consider  $x \geq 0.0$

The routine is based on three Chebyshev expansions:

For  $0 < x \leq 3$ ,

$$C(x) = x \int_0^1 a_r T_r(t) dt, \text{ with } t = \frac{x}{3} - 1;$$

For  $x > 3$ ,

$$C(x) = \frac{1}{2} \frac{f(x)}{x} \sin\left(\frac{\pi}{2} x\right) - \frac{g(x)}{3x} \cos\left(\frac{\pi}{2} x\right),$$

where  $f(x) = \int_0^1 b_r T_r(t) dt,$

and  $g(x) = \int_0^1 c_r T_r(t) dt, \text{ with } t = \frac{3}{x} - 1.$

For small  $x$ ,  $C(x) \sim x$ . This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision.

For large  $x$ ,  $f(x) \sim \frac{1}{\pi}$  and  $g(x) \sim \frac{1}{2}$ . Therefore for

moderately large  $x$ , when  $\frac{1}{2^3} \frac{(\pi)^2}{x}$  is negligible compared with  $\frac{1}{2}$ , the second term in the approximation for  $x > 3$  may be dropped. For very large  $x$ , when  $\frac{1}{(\pi)x}$  becomes negligible,  $C(x) \sim \frac{1}{2}$ . However there will be considerable difficulties in calculating  $\sin\left(\frac{(\pi)^2}{2} x\right)$  accurately before this final limiting value can be used. Since  $\sin\left(\frac{(\pi)^2}{2} x\right)$  is periodic, its value is essentially determined by the fractional part of  $x$ . If  $x = N + (\theta)$ , where  $N$  is an integer and  $0 \leq (\theta) < 1$ , then  $\sin\left(\frac{(\pi)^2}{2} x\right)$  depends on  $(\theta)$  and on  $N$  modulo 4. By exploiting this fact, it is possible to retain some significance in the calculation of  $\sin\left(\frac{(\pi)^2}{2} x\right)$  either all the way to the very large  $x$  limit, or at least until the integer part of  $\frac{x}{2}$  is equal to the maximum integer allowed on the machine.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
 On entry: the argument  $x$  of the function.
- 2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL has been included for consistency with other routines in this chapter.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e if (delta) is due to data errors etc), then (epsilon) and (delta) are approximately related by:

$$(\epsilon) \sim \frac{(\pi)^2 |x \cos(x)|}{C(x)} (\delta)$$

Figure 1 shows the behaviour of the error amplification factor

$$\frac{(\pi)^2 |x \cos(x)|}{C(x)}$$

Figure 1

Please see figure in printed Reference Manual

However if (delta) is of the same order as the machine precision, then rounding errors could make (epsilon) slightly larger than the above relation predicts.

For small x, (epsilon)~=(delta) and there is no amplification of relative error.

For moderately large values of x,

$$|(\epsilon)| \sim 2|x \cos(x)| (\delta)$$

and the result will be subject to increasingly large amplification of errors. However the above relation breaks down

1  
for large values of x (i.e., when -- is of the order of the  
2

machine precision); in this region the relative error in the  

$$\frac{x}{2}$$
result is essentially bounded by  $-----$ ).  
 $(\pi)x$

Hence the effects of error amplification are limited and at worst the relative error loss should not exceed half the possible number of significant figures.

#### 8. Further Comments

None.

#### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S21 -- Approximations of Special Functions S21BAF  
S21BAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S21BAF returns a value of an elementary integral, which occurs as a degenerate case of an elliptic integral of the first kind, via the routine name.

#### 2. Specification

```
DOUBLE PRECISION FUNCTION S21BAF (X, Y, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X, Y
```

#### 3. Description

This routine calculates an approximate value for the integral

$\int_0^x$

$$R_C(x,y) = \int_0^1 \frac{dt}{\sqrt{t+x(t+y)}}$$

where  $x \geq 0$  and  $y \neq 0$ .

This function, which is related to the logarithm or inverse hyperbolic functions for  $y < x$  and to inverse circular functions if  $x < y$ , arises as a degenerate form of the elliptic integral of the first kind. If  $y < 0$ , the result computed is the Cauchy principal value of the integral.

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the system:

$$\begin{aligned} x_{n+1} &= x_n \\ y_{n+1} &= y_n \\ \mu_n &= (x_n + 2y_n) / 3 \\ S_n &= (y_n - x_n) / (3\mu_n) \\ \lambda_n &= y_n + 2\sqrt{x_n y_n} \\ x_{n+1} &= (x_n + \lambda_n) / 4 \\ y_{n+1} &= (y_n + \lambda_n) / 4 \end{aligned}$$

The quantity  $|S_n|$  for  $n=0,1,2,3,\dots$  decreases with increasing  $n$ , eventually  $|S_n| \sim 1/4$ . For small enough  $S_n$  the required function value can be approximated by the first few terms of the Taylor series about the mean. That is

$$\begin{pmatrix} 2 & 3 & 4 & 5 \\ 3S & S & 3S & 9S \end{pmatrix}$$

$$R(x,y) = \frac{(1 + \frac{x^n}{10} + \frac{y^n}{7} + \frac{x^{2n}}{8} + \frac{y^{2n}}{22})^{\frac{1}{n}}}{C}$$

The truncation error involved in using this approximation is bounded by  $16|S|^6 / (1-2|S|)$  and the recursive process is stopped when  $S$  is small enough for this truncation error to be negligible compared to the machine precision.

Within the domain of definition, the function value is itself representable for all representable values of its arguments. However, for values of the arguments near the extremes the above algorithm must be modified so as to avoid causing underflows or overflows in intermediate steps. In extreme regions arguments are pre-scaled away from the extremes and compensating scaling of the result is done before returning to the calling program.

- [3] Carlson B C (1988) A Table of Elliptic Integrals of the Third Kind. Math. Comput. 51 267--280.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input
- 2: Y -- DOUBLE PRECISION Input  
 On entry: the arguments x and y of the function, respectively. Constraint: X >= 0.0 and Y /= 0.0.
- 3: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1  
 On entry X < 0.0; the function is undefined.

IFAIL= 2  
 On entry Y = 0.0; the function is undefined.

On soft failure the routine returns zero.

7. Accuracy

In principle the routine is capable of producing full machine precision. However round-off errors in internal arithmetic will result in slight loss of accuracy. This loss should never be excessive as the algorithm does not involve any significant amplification of round-off error. It is reasonable to assume that the result is accurate to within a small multiple of the machine precision.

8. Further Comments

Users should consult the Chapter Introduction which shows the relationship of this function to the classical definitions of the elliptic integrals.

9. Example

This example program simply generates a small set of non-extreme arguments which are used with the routine to produce the table of low accuracy results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S21 -- Approximations of Special Functions S21BBF  
 S21BBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S21BBF returns a value of the symmetrised elliptic integral of the first kind, via the routine name.

## 2. Specification

```
DOUBLE PRECISION FUNCTION S21BBF (X, Y, Z, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X, Y, Z
```

## 3. Description

This routine calculates an approximation to the integral

$$R(x,y,z) = \int_0^{\infty} \frac{dt}{\sqrt{(t+x)(t+y)(t+z)}}$$

where  $x, y, z \geq 0$  and at most one is zero.

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the rule:

$$x = \min(x,y,z), z = \max(x,y,z),$$

$$y = \text{remaining third intermediate value argument.}$$

(This ordering, which is possible because of the symmetry of the function, is done for technical reasons related to the avoidance of overflow and underflow.)

$$\mu = \frac{(x+y+3z)}{3}$$

$$X = \frac{(1-x)}{\mu}$$

$$Y = \frac{(1-y)}{\mu}$$

$$Z = \frac{(1-z)}{\mu}$$

$$\lambda = \sqrt{x y} + \sqrt{y z} + \sqrt{z x}$$

$$x_{n+1} = \frac{x + (\lambda)^n}{4}$$

$$y_{n+1} = \frac{y + (\lambda)^n}{4}$$

$$z_{n+1} = \frac{z + (\lambda)^n}{4}$$

(epsilon) = max(|X<sub>n</sub> |, |Y<sub>n</sub> |, |Z<sub>n</sub> |) and the function may be approximated adequately by a 5th order power series:

$$R(x,y,z) = \frac{1}{F} \frac{(\begin{matrix} 2 \\ E^2 E^2 3E^2 E^2 \end{matrix})}{(\begin{matrix} 2 & 2 & 2 & 3 & 3 \\ 10 & 24 & 44 & 14 \end{matrix})} (1 - \frac{\epsilon}{10} + \frac{\epsilon^2}{24} - \frac{\epsilon^3}{44} + \frac{\epsilon^4}{14} - \dots)$$

$$\frac{1}{F} \frac{1}{\sqrt{\mu}}$$

where E<sub>2</sub> = X<sup>2</sup> Y + Y<sup>2</sup> Z + Z<sup>2</sup> X , E<sub>3</sub> = X<sup>3</sup> Y Z .

The truncation error involved in using this approximation is bounded by (epsilon)<sup>6</sup> / 4(1-(epsilon)<sup>n</sup>) and the recursive process is stopped when this truncation error is negligible compared with the machine precision.

Within the domain of definition, the function value is itself representable for all representable values of its arguments. However, for values of the arguments near the extremes the above algorithm must be modified so as to avoid causing underflows or overflows in intermediate steps. In extreme regions arguments are pre-scaled away from the extremes and compensating scaling of the result is done before returning to the calling program.

#### 5. Parameters

1: X -- DOUBLE PRECISION Input

2: Y -- DOUBLE PRECISION Input

3: Z -- DOUBLE PRECISION Input

On entry: the arguments  $x$ ,  $y$  and  $z$  of the function.

Constraint:  $X, Y, Z \geq 0.0$  and only one of  $X, Y$  and  $Z$  may be zero.

4: IFAIL -- INTEGER Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry one or more of  $X, Y$  and  $Z$  is negative; the function is undefined.

IFAIL= 2

On entry two or more of  $X, Y$  and  $Z$  are zero; the function is undefined.

On soft failure, the routine returns zero.

#### 7. Accuracy

In principle the routine is capable of producing full machine precision. However round-off errors in internal arithmetic will result in slight loss of accuracy. This loss should never be excessive as the algorithm does not involve any significant amplification of round-off error. It is reasonable to assume that the result is accurate to within a small multiple of the machine precision.

#### 8. Further Comments

Users should consult the Chapter Introduction which shows the relationship of this function to the classical definitions of the elliptic integrals.

If two arguments are equal, the function reduces to the elementary integral  $R$ , computed by S21BAF.

C

9. Example

This example program simply generates a small set of non-extreme arguments which are used with the routine to produce the table of low accuracy results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S21 -- Approximations of Special Functions S21BCF  
 S21BCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S21BCF returns a value of the symmetrised elliptic integral of the second kind, via the routine name.

2. Specification

DOUBLE PRECISION FUNCTION S21BCF (X, Y, Z, IFAIL)  
 INTEGER IFAIL  
 DOUBLE PRECISION X, Y, Z

3. Description

This routine calculates an approximate value for the integral

$$R_D(x,y,z) = \int_0^{\infty} \frac{dt}{\sqrt{(t+x)(t+y)(t+z)^3}}$$

where  $x, y \geq 0$ , at most one of  $x$  and  $y$  is zero, and  $z > 0$ .

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the rule:

$$x_0 = x$$

$$y_0 = y$$

$$z_0 = z$$

$$(\mu)_n = (x_n + y_n + 3z_n) / 5$$

$$X_n = (1 - x_n) / (\mu)_n$$

$$Y_n = (1 - y_n) / (\mu)_n$$

$$Z_n = (1 - z_n) / (\mu)_n$$

$$(\lambda)_n = \sqrt[n]{x_n y_n} + \sqrt[n]{y_n z_n} + \sqrt[n]{z_n x_n}$$

$$x_{n+1} = (x_n + (\lambda)_n) / 4$$

$$y_{n+1} = (y_n + (\lambda)_n) / 4$$

$$z_{n+1} = (z_n + (\lambda)_n) / 4$$

For  $n$  sufficiently large,

$$(\epsilon)_n = \max(|X_n|, |Y_n|, |Z_n|) \sim \left( \frac{1}{4} \right)^n \quad (4)$$

and the function may be approximated adequately by a 5th order

$$\frac{n-1}{4} - m$$

- [3] Carlson B C (1988) A Table of Elliptic Integrals of the Third Kind. Math. Comput. 51 267--280.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input
- 2: Y -- DOUBLE PRECISION Input
- 3: Z -- DOUBLE PRECISION Input  
 On entry: the arguments  $x$ ,  $y$  and  $z$  of the function.  
 Constraint:  $X, Y \geq 0.0$ ,  $Z > 0.0$  and only one of  $X$  and  $Y$  may be zero.

- 4: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry either  $X$  or  $Y$  is negative, or both  $X$  and  $Y$  are zero; the function is undefined.

IFAIL= 2

On entry  $Z \leq 0.0$ ; the function is undefined.

IFAIL= 3

On entry either  $Z$  is too close to zero or both  $X$  and  $Y$  are too close to zero: there is a danger of setting overflow.

IFAIL= 4

On entry at least one of  $X$ ,  $Y$  and  $Z$  is too large: there is a danger of setting underflow.

On soft failure the routine returns zero.

#### 7. Accuracy

In principle the routine is capable of producing full machine

precision. However round-off errors in internal arithmetic will result in slight loss of accuracy. This loss should never be excessive as the algorithm does not involve any significant amplification of round-off error. It is reasonable to assume that the result is accurate to within a small multiple of the machine precision.

8. Further Comments

Users should consult the Chapter Introduction which shows the relationship of this function to the classical definitions of the elliptic integrals.

9. Example

This example program simply generates a small set of non-extreme arguments which are used with the routine to produce the table of low accuracy results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S21 -- Approximations of Special Functions S21BDF  
 S21BDF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S21BDF returns a value of the symmetrised elliptic integral of the third kind, via the routine name.

2. Specification

```

    DOUBLE PRECISION FUNCTION S21BDF (X, Y, Z, R, IFAIL)
    INTEGER          IFAIL
    DOUBLE PRECISION X, Y, Z, R
    
```

3. Description

This routine calculates an approximation to the integral

$$\int_0^{\text{infty}} \frac{dt}{3 + dt}$$

$$R(x,y,z,(\rho)) = - \int_0^{\rho} \frac{dt}{(t+\rho)\sqrt{(t+x)(t+y)(t+z)}}$$

where  $x, y, z \geq 0$ ,  $(\rho) \neq 0$  and at most one of  $x, y$  and  $z$  is zero.

If  $p < 0$ , the result computed is the Cauchy principal value of the integral.

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the rule:

$$x_0 = x$$

$$y_0 = y$$

$$z_0 = z$$

$$(\rho)_0 = (\rho)$$

$$(\mu)_n = (x_n + y_n + z_n + 2(\rho)_n) / 5$$

$$X_n = (1 - x_n) / (\mu)_n$$

$$Y_n = (1 - y_n) / (\mu)_n$$

$$Z_n = (1 - z_n) / (\mu)_n$$

$$P_n = (1 - (\rho)_n) / (\mu)_n$$

$$(\lambda)_n = \sqrt[3]{x_n y_n z_n} + \sqrt[3]{y_n z_n x_n} + \sqrt[3]{z_n x_n y_n}$$

$$x_{n+1} = (x_n + (\lambda)_n) / 4$$

$$y_{n+1} = (y_n + (\lambda)_n) / 4$$

$$z_{n+1} = (z_n + (\lambda)_n) / 4$$

$$(\rho)_{n+1} = ((\rho)_n + (\lambda)_n) / 4$$

$$(\alpha)_n = [(\rho)_n ( \sqrt{x_n} + \sqrt{y_n} + \sqrt{z_n} ) + \sqrt{x_n y_n z_n}]^2$$

$$(\beta)_n = (\rho)_n ((\rho)_n + (\lambda)_n)^2$$

For n sufficiently large,

$$(\epsilon)_n = \max(|X_n|, |Y_n|, |Z_n|, |P_n|) \sim \frac{1}{4^n}$$

and the function may be approximated by a 5th order power series

$$R(x,y,z,(\rho)) = \sum_{m=0}^{n-1} \frac{C_m}{J} R((\alpha)_m, (\beta)_m)$$

$$+ \frac{1}{\sqrt{\mu}} \frac{1}{n^3} [ 1 + \frac{S_1}{7n} - \frac{S_2}{3n} + \frac{S_3}{22n} - \frac{S_4}{11n} + \frac{S_5}{13n} + \frac{S_6}{13n} ]$$

where  $S_m = (X^m + Y^m + Z^m + 2P^m) / 2m$ .

The truncation error in this expansion is bounded by

$$3(\epsilon)_n / \sqrt{(1 - (\epsilon)_n)^3}$$

and the recursion process is terminated when this quantity is negligible compared with the machine precision. The routine may fail either because it has been called with arguments outside the domain of definition or

with arguments so extreme that there is an unavoidable danger of setting underflow or overflow.

$$\frac{3}{2}$$

Note:  $R(x, x, x, x) = x^J$ , so there exists a region of extreme arguments for which the function value is not representable.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input
- 2: Y -- DOUBLE PRECISION Input
- 3: Z -- DOUBLE PRECISION Input
- 4: R -- DOUBLE PRECISION Input  
 On entry: the arguments x, y, z and (rho) of the function.  
 Constraint: X, Y, Z >= 0.0, R /= 0.0 and at most one of X, Y and Z may be zero.
- 5: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry at least one of X, Y and Z is negative, or at least two of them are zero; the function is undefined.

IFAIL= 2

On entry  $R = 0.0$ ; the function is undefined.

IFAIL= 3

On entry either R is too close to zero, or any two of X, Y and Z are too close to zero; there is a danger of setting overflow.

IFAIL= 4

On entry at least one of X, Y, Z and R is too large; there is a danger of setting underflow.

IFAIL= 5

An error has occurred in a call to S21BAF. Any such occurrence should be reported to NAG.

On soft failure, the routine returns zero.

#### 7. Accuracy

In principle the routine is capable of producing full machine precision. However round-off errors in internal arithmetic will result in slight loss of accuracy. This loss should never be excessive as the algorithm does not involve any significant amplification of round-off error. It is reasonable to assume that the result is accurate to within a small multiple of the machine precision.

#### 8. Further Comments

Users should consult the Chapter Introduction which shows the relationship of this function to the classical definitions of the elliptic integrals.

If the argument R is equal to any of the other arguments, the function reduces to the integral  $R$ , computed by S21BCF.

D

#### 9. Example

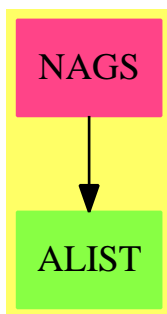

This example program simply generates a small set of non-extreme arguments which are used with the routine to produce the table of low accuracy results.

The example program is not reproduced here. The source code for

all example programs is distributed with the NAG Foundation Library software and should be available on-line.

++ s18adf(x,ifail)
++ returns the value of the modified Bessel Function
++ K (x), via the routine name.
++ 1
++ See \downlink{Manual Page}{manpageXXs18adf}.
s18aef : (DoubleFloat,Integer) -> Result
++ s18aef(x,ifail)
++ returns the value of the modified Bessel Function
++ I (x), via the routine name.
++ 0
++ See \downlink{Manual Page}{manpageXXs18aef}.
s18aff : (DoubleFloat,Integer) -> Result
++ s18aff(x,ifail)
++ returns a value for the modified Bessel Function
++ I (x), via the routine name.
++ 1
++ See \downlink{Manual Page}{manpageXXs18aff}.
s18dcf : (DoubleFloat,Complex DoubleFloat,Integer,String,
Integer) -> Result
++ s18dcf(fnu,z,n,scale,ifail)
++ returns a sequence of values for the modified Bessel functions
++ K (z) for complex z, non-negative (nu) and

```

```

++      (nu)+n
++ n=0,1,...,N-1, with an option for exponential scaling.
++ See \downlink{Manual Page}{manpageXXs18dcf}.
s18def : (DoubleFloat,Complex DoubleFloat,Integer,String,
Integer) -> Result
++ s18def(fnu,z,n,scale,ifail)
++ returns a sequence of values for the modified Bessel functions
++  $I_\nu(z)$  for complex  $z$ , non-negative  $(\nu)$  and
++      (nu)+n
++ n=0,1,...,N-1, with an option for exponential scaling.
++ See \downlink{Manual Page}{manpageXXs18def}.
s19aaf : (DoubleFloat,Integer) -> Result
++ s19aaf(x,ifail)
++ returns a value for the Kelvin function ber(x) via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs19aaf}.
s19abf : (DoubleFloat,Integer) -> Result
++ s19abf(x,ifail)
++ returns a value for the Kelvin function bei(x) via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs19abf}.
s19acf : (DoubleFloat,Integer) -> Result
++ s19acf(x,ifail)
++ returns a value for the Kelvin function ker(x), via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs19acf}.
s19adf : (DoubleFloat,Integer) -> Result
++ s19adf(x,ifail)
++ returns a value for the Kelvin function kei(x) via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs19adf}.
s20acf : (DoubleFloat,Integer) -> Result
++ s20acf(x,ifail)
++ returns a value for the Fresnel Integral  $S(x)$ , via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs20acf}.
s20adf : (DoubleFloat,Integer) -> Result
++ s20adf(x,ifail)
++ returns a value for the Fresnel Integral  $C(x)$ , via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs20adf}.
s21baf : (DoubleFloat,DoubleFloat,Integer) -> Result
++ s21baf(x,y,ifail)
++ returns a value of an elementary integral, which occurs as
++ a degenerate case of an elliptic integral of the first kind, via
++ the routine name.
++ See \downlink{Manual Page}{manpageXXs21baf}.
s21bbf : (DoubleFloat,DoubleFloat,DoubleFloat,Integer) -> Result
++ s21bbf(x,y,z,ifail)
++ returns a value of the symmetrised elliptic integral of

```

```

++ the first kind, via the routine name.
++ See \downlink{Manual Page}{manpageXXs21bbf}.
s21bcf : (DoubleFloat,DoubleFloat,DoubleFloat,Integer) -> Result
++ s21bcf(x,y,z,ifail)
++ returns a value of the symmetrised elliptic integral of
++ the second kind, via the routine name.
++ See \downlink{Manual Page}{manpageXXs21bcf}.
s21bdf : (DoubleFloat,DoubleFloat,DoubleFloat,DoubleFloat,
Integer) -> Result
++ s21bdf(x,y,z,r,ifail)
++ returns a value of the symmetrised elliptic integral of
++ the third kind, via the routine name.
++ See \downlink{Manual Page}{manpageXXs21bdf}.
Implementation ==> add

## NumberFieldIntegralBasis (NFINTBAS)

**Exports:**

discriminant integralBasis localIntegralBasis

— package NFINTBAS NumberFieldIntegralBasis —

```

)abbrev package NFINTBAS NumberFieldIntegralBasis
++ Author: Victor Miller, Clifton Williamson
++ Date Created: 9 April 1990
++ Date Last Updated: 20 September 1994
++ Description:
++ In this package F is a framed algebra over the integers (typically
++ \spad{F = Z[a]} for some algebraic integer a). The package provides
++ functions to compute the integral closure of Z in the quotient
++ quotient field of F.

NumberFieldIntegralBasis(UP,F): Exports == Implementation where
  UP : UnivariatePolynomialCategory Integer
  F : FramedAlgebra(Integer,UP)

FR ==> Factored Integer
I ==> Integer
Mat ==> Matrix I
NNI ==> NonNegativeInteger
Ans ==> Record(basis: Mat, basisDen: I, basisInv:Mat,discr: I)

Exports ==> with
  discriminant: () -> Integer
  ++ \spad{discriminant()} returns the discriminant of the integral
  ++ closure of Z in the quotient field of the framed algebra F.
  integralBasis : () -> Record(basis: Mat, basisDen: I, basisInv:Mat)
  ++ \spad{integralBasis()} returns a record
  ++ \spad{[basis,basisDen,basisInv]}
  ++ containing information regarding the integral closure of Z in the
  ++ quotient field of F, where F is a framed algebra with Z-module
  ++ basis \spad{w1,w2,...,wn}.

```

```

++ If \spad{basis} is the matrix \spad{(aij, i = 1..n, j = 1..n)}, then
++ the \spad{i}th element of the integral basis is
++ \spad{vi = (1/basisDen) * sum(aij * wj, j = 1..n)}, i.e. the
++ \spad{i}th row of \spad{basis} contains the coordinates of the
++ \spad{i}th basis vector. Similarly, the \spad{i}th row of the
++ matrix \spad{basisInv} contains the coordinates of \spad{wi} with
++ respect to the basis \spad{v1,...,vn}: if \spad{basisInv} is the
++ matrix \spad{(bij, i = 1..n, j = 1..n)}, then
++ \spad{wi = sum(bij * vj, j = 1..n)}.
localIntegralBasis : I -> Record(basis: Mat, basisDen: I, basisInv:Mat)
++ \spad{integralBasis(p)} returns a record
++ \spad{[basis,basisDen,basisInv]} containing information regarding
++ the local integral closure of Z at the prime \spad{p} in the quotient
++ field of F, where F is a framed algebra with Z-module basis
++ \spad{w1,w2,...,wn}.
++ If \spad{basis} is the matrix \spad{(aij, i = 1..n, j = 1..n)}, then
++ the \spad{i}th element of the integral basis is
++ \spad{vi = (1/basisDen) * sum(aij * wj, j = 1..n)}, i.e. the
++ \spad{i}th row of \spad{basis} contains the coordinates of the
++ \spad{i}th basis vector. Similarly, the \spad{i}th row of the
++ matrix \spad{basisInv} contains the coordinates of \spad{wi} with
++ respect to the basis \spad{v1,...,vn}: if \spad{basisInv} is the
++ matrix \spad{(bij, i = 1..n, j = 1..n)}, then
++ \spad{wi = sum(bij * vj, j = 1..n)}.

=====  
 NumericalOrdinaryDifferentialEquations examples  
 =====

This package is a suite of functions for the numerical integration of an ordinary differential equation of n variables:

$$dy/dx = f(y,x) \quad y \text{ is an } n\text{-vector}$$

All the routines are based on a 4-th order Runge-Kutta kernel.

These routines generally have as arguments:

- n, the number of dependent variables;\br
- x1, the initial point;\br
- h, the step size;\br
- y, a vector of initial conditions of length n\br

which upon exit contains the solution at x1 + h

derivs, a function which computes the right hand side of the ordinary differential equation:

```
derivs(dydx,y,x)
```

computes dydx, a vector which contains the derivative information.

In order of increasing complexity:

```
rk4(y,n,x1,h,derivs)
```

advances the solution vector to

`x1 + h`

and return the values in `y`.

`rk4(y,n,x1,h,derivs,t1,t2,t3,t4)`

is the same as

`rk4(y,n,x1,h,derivs)`

except that you must provide 4 scratch

arrays `t1-t4` of size `n`

Starting with `y` at `x1`,

`rk4f(y,n,x1,x2,ns,derivs)`

uses `ns` fixed steps of a 4-th order Runge-Kutta integrator to advance the solution vector to `x2` and return the values in `y`. Argument `x2`, is the final point, and `ns`, the number of steps to take.

`rk4qc(y,n,x1,step,eps,yscal,derivs)`

takes a 5-th order Runge-Kutta step with monitoring of local truncation to ensure accuracy and adjust stepsize.

The function takes two half steps and one full step and scales the difference in solutions at the final point. If the error is within `eps`, the step is taken and the result is returned.

If the error is not within `eps`, the stepsize is decreased and the procedure is tried again until the desired accuracy is reached. Upon input, a trial step size must be given and upon return, an estimate of the next step size to use is returned as well as the step size which produced the desired accuracy.

The scaled error is computed as

`error = MAX(ABS((y2steps(i) - y1step(i))/yscal(i)))`

and this is compared against `eps`. If this is greater than `eps`, the step size is reduced accordingly to

`hnew = 0.9 * hdid * (error/eps)**(-1/4)`

If the error criterion is satisfied, then we check if the step size was too fine and return a more efficient one. If

`error > eps * (6.0E-04)`

then the next step size should be

$$h_{next} = 0.9 * h_{did} * (error/eps)**(-1/5)$$

Otherwise

$$h_{next} = 4.0 * h_{did}$$

is returned.

A more detailed discussion of this and related topics can be found in the book "Numerical Recipes" by W.Press, B.P. Flannery, S.A. Teukolsky, W.T. Vetterling published by Cambridge University Press.

Argument `step` is a record of 3 floating point numbers (`try`, `did`, `next`), `eps` is the required accuracy, `yscal` is the scaling vector for the difference in solutions.

On input, `step.try` should be the guess at a step size to achieve the accuracy. On output, `step.did` contains the step size which achieved the accuracy and `step.next` is the next step size to use.

$$rk4qc(y,n,x1,step,eps,yscal,derivs,t1,t2,t3,t4,t5,t6,t7)$$

is the same as

$$rk4qc(y,n,x1,step,eps,yscal,derivs)$$

except that the user must provide the 7 scratch arrays `t1-t7` of size `n`.

$$rk4a(y,n,x1,x2,eps,h,ns,derivs)$$

is a driver program which uses `rk4qc` to integrate `n` ordinary differential equations starting at `x1` to `x2`, keeping the local truncation error to within `eps` by changing the local step size.

The scaling vector is defined as

$$yscal(i) = abs(y(i)) + abs(h*dydx(i)) + tiny$$

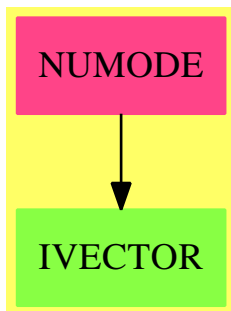

where `y(i)` is the solution at location `x`, `dydx` is the ordinary differential equation's right hand side, `h` is the current step size and `tiny` is 10 times the smallest positive number representable.

The user must supply an estimate for a trial step size and the maximum number of calls to `rk4qc` to use. Argument `x2` is the final point, `eps` is local truncation, `ns` is the maximum number of call to `rk4qc` to use.

)abbrev package NUMODE NumericalOrdinaryDifferentialEquations
++ Author: Yurij Baransky
++ Date Created: October 90
++ Date Last Updated: October 90
++ Description:
++ This package is a suite of functions for the numerical integration of an
++ ordinary differential equation of n variables:\br
++ \tab{5}dy/dx = f(y,x)\tab{5}y is an n-vector\br
++ All the routines are based on a 4-th order Runge-Kutta kernel.
++ These routines generally have as arguments:\br
++ n, the number of dependent variables;\br
++ x1, the initial point;\br
++ h, the step size;\br
++ y, a vector of initial conditions of length n\br
++ which upon exit contains the solution at \spad{x1 + h};\br
++
++ \spad{derivs}, a function which computes the right hand side of the
++ ordinary differential equation: \spad{derivs(dydx,y,x)} computes
++ \spad{dydx}, a vector which contains the derivative information.
++
++ In order of increasing complexity:\br
++ \tab{5}\spad{rk4(y,n,x1,h,derivs)} advances the solution vector to\br

```

```

++ \tab{5}\spad{x1 + h} and return the values in y.\br
++
++ \tab{5}\spad{rk4(y,n,x1,h,derivs,t1,t2,t3,t4)} is the same as\br
++ \tab{5}\spad{rk4(y,n,x1,h,derivs)} except that you must provide 4 scratch\br
++ \tab{5}arrays t1-t4 of size n.\br
++
++ \tab{5}Starting with y at x1, \spad{rk4f(y,n,x1,x2,ns,derivs)}\br
++ \tab{5}uses \spad{ns} fixed steps of a 4-th order Runge-Kutta\br
++ \tab{5}integrator to advance the solution vector to x2 and return\br
++ \tab{5}the values in y. Argument x2, is the final point, and\br
++ \tab{5}\spad{ns}, the number of steps to take.
++
++ \spad{rk4qc(y,n,x1,step,eps,yscal,derivs)} takes a 5-th order
++ Runge-Kutta step with monitoring of local truncation to ensure
++ accuracy and adjust stepsize.
++ The function takes two half steps and one full step and scales
++ the difference in solutions at the final point. If the error is
++ within \spad{eps}, the step is taken and the result is returned.
++ If the error is not within \spad{eps}, the stepsize is decreased
++ and the procedure is tried again until the desired accuracy is
++ reached. Upon input, an trial step size must be given and upon
++ return, an estimate of the next step size to use is returned as
++ well as the step size which produced the desired accuracy.
++ The scaled error is computed as\br

```

++ \spad{rk4a(y,n,x1,x2,eps,h,ns,derivs)}
++ is a driver program which uses \spad{rk4qc} to integrate n ordinary
++ differential equations starting at x1 to x2, keeping the local
++ truncation error to within \spad{eps} by changing the local step size.
++ The scaling vector is defined as\br
++ \tab{5}\spad{yscal(i) = abs(y(i)) + abs(h*dydx(i)) + tiny}\br
++ where \spad{y(i)} is the solution at location x, \spad{dydx} is the
++ ordinary differential equation's right hand side, h is the current
++ step size and \spad{tiny} is 10 times the
++ smallest positive number representable.
++
++ The user must supply an estimate for a trial step size and
++ the maximum number of calls to \spad{rk4qc} to use.
++ Argument x2 is the final point,
++ \spad{eps} is local truncation,
++ \spad{ns} is the maximum number of call to \spad{rk4qc} to use.

NumericalQuadrature examples

=====

This suite of routines performs numerical quadrature using algorithms derived from the basic trapezoidal rule. Because the error term of this rule contains only even powers of the step size (for open and closed versions), fast convergence can be obtained if the integrand is sufficiently smooth.

Each routine returns a Record of type TrapAns, which contains

|                   |                                                                        |
|-------------------|------------------------------------------------------------------------|
| value Float:      | estimate of the integral                                               |
| error Float:      | estimate of the error in the computation                               |
| totalpts Integer: | total number of function evaluations                                   |
| success Boolean:  | if the integral was computed within the user specified error criterion |

To produce this estimate, each routine generates an internal sequence of sub-estimates, denoted by S(i), depending on the

routine, to which the various convergence criteria are applied. The user must supply a relative accuracy, `eps_r`, and an absolute accuracy, `eps_a`. Convergence is obtained when either

```

      ABS(S(i) - S(i-1)) < eps_r * ABS(S(i-1))
or
      ABS(S(i) - S(i-1)) < eps_a
are true statements.

```

The routines come in three families and three flavors:

```

closed: romberg, simpson, trapezoidal
open:  rombergo, simpsono, trapezoidal
adaptive closed: aromberg, asimpson, atrapezoidal

```

The  $S(i)$  for the trapezoidal family is the value of the integral using an equally spaced abscissa trapezoidal rule for that level of refinement.

The  $S(i)$  for the simpson family is the value of the integral using an equally spaced abscissa simpson rule for that level of refinement.

The  $S(i)$  for the romberg family is the estimate of the integral using an equally spaced abscissa romberg method. For the  $i$ -th level, this is an appropriate combination of all the previous trapezoidal estimates so that the error term starts with the  $2^{*(i+1)}$  power only.

The three families come in a closed version, where the formulas include the endpoints, an open version where the formulas do not include the endpoints and an adaptive version, where the user is required to input the number of subintervals over which the appropriate closed family integrator will apply with the usual convergence parameters for each subinterval. This is useful where a large number of points are needed only in a small fraction of the entire domain.

Each routine takes as arguments:

```

f integrand
a starting point
b ending point
eps_r relative error
eps_a absolute error
nmin refinement level when to start checking for convergence (> 1)
nmax maximum level of refinement

```

The adaptive routines take as an additional parameter, `nint`, the number of independent intervals to apply a closed family integrator of the same name.

Note that closed family level  $i$  uses  $1 + 2^{*i}$  points.

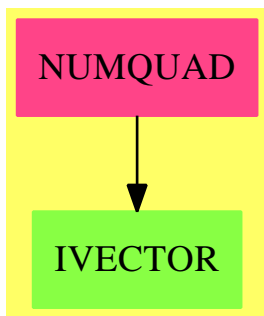

Open family level  $i$  uses  $1 + 3^{*i}$  points.

++ Author: Yurij A. Baransky
++ Date Created: October 90
++ Date Last Updated: October 90
++ Description:
++ This suite of routines performs numerical quadrature using
++ algorithms derived from the basic trapezoidal rule. Because
++ the error term of this rule contains only even powers of the
++ step size (for open and closed versions), fast convergence
++ can be obtained if the integrand is sufficiently smooth.
++
++ Each routine returns a Record of type TrapAns, which contains
++ value Float: estimate of the integral
++ error Float: estimate of the error in the computation
++ totalpts Integer: total number of function evaluations
++ success Boolean: if the integral was computed within the user
++ specified error criterion
++ To produce this estimate, each routine generates an internal
++ sequence of sub-estimates, denoted by S(i), depending on the
++ routine, to which the various convergence criteria are applied.
++ The user must supply a relative accuracy, \spad{eps_r}, and an absolute
++ accuracy, \spad{eps_a}. Convergence is obtained when either\br
  
```

```

++ \tab{5}\spad{ABS(S(i) - S(i-1)) < eps_r * ABS(S(i-1))}\br
++ \tab{5}or \spad{ABS(S(i) - S(i-1)) < eps_a}
++ are true statements.
++
++ The routines come in three families and three flavors:
++ closed: romberg, simpson, trapezoidal
++ open: rombergo, simpsono, trapezoidalo
++ adaptive closed: aromberg, asimpson, atrapezoidal
++
++ The S(i) for the trapezoidal family is the value of the
++ integral using an equally spaced absicca trapezoidal rule for
++ that level of refinement.
++
++ The S(i) for the simpson family is the value of the integral
++ using an equally spaced absicca simpson rule for that level of
++ refinement.
++
++ The S(i) for the romberg family is the estimate of the integral
++ using an equally spaced absicca romberg method. For
++ the i-th level, this is an appropriate combination of all the
++ previous trapezodial estimates so that the error term starts
++ with the 2*(i+1) power only.
++
++ The three families come in a closed version, where the formulas
++ include the endpoints, an open version where the formulas do not
++ include the endpoints and an adaptive version, where the user
++ is required to input the number of subintervals over which the
++ appropriate closed family integrator will apply with the usual
++ convergence parmeters for each subinterval. This is useful
++ where a large number of points are needed only in a small fraction
++ of the entire domain.

simpson      : (F -> F,F,F,F,F,I,I) -> TrapAns
  ++ simpson(fn,a,b,epsrel,epsabs,nmin,nmax) uses the simpson
  ++ method to numerically integrate function \spad{fn} over the closed
  ++ interval \spad{a} to \spad{b}, with
  ++ relative accuracy \spad{epsrel} and absolute accuracy \spad{epsabs},
  ++ with the refinement levels for convergence checking vary from
  ++ \spad{nmin} to \spad{nmax}. The value returned
  ++ is a record containing the value of the integral, the estimate of
  ++ the error in the computation, the total number of function
  ++ evaluations, and either a boolean value which is true if
  ++ the integral was computed within the user specified error criterion.
  ++ See \spadtype{NumericalQuadrature} for details.
trapezoidal : (F -> F,F,F,F,F,I,I) -> TrapAns
  ++ trapezoidal(fn,a,b,epsrel,epsabs,nmin,nmax) uses the
  ++ trapezoidal method to numerically integrate function \spadvar{fn} over
  ++ the closed interval \spad{a} to \spad{b}, with relative accuracy
  ++ \spad{epsrel} and absolute accuracy \spad{epsabs}, with the
  ++ refinement levels for convergence checking vary
  ++ from \spad{nmin} to \spad{nmax}. The value
  ++ returned is a record containing the value of the integral, the
  ++ estimate of the error in the computation, the total number of
  ++ function evaluations, and either a boolean value which is true
  ++ if the integral was computed within the user specified error criterion.
  ++ See \spadtype{NumericalQuadrature} for details.
rombergo     : (F -> F,F,F,F,F,I,I) -> TrapAns
  ++ rombergo(fn,a,b,epsrel,epsabs,nmin,nmax) uses the romberg
  ++ method to numerically integrate function \spad{fn} over
  ++ the open interval from \spad{a} to \spad{b}, with
  ++ relative accuracy \spad{epsrel} and absolute accuracy \spad{epsabs},
  ++ with the refinement levels for convergence checking vary from
  ++ \spad{nmin} to \spad{nmax}. The value returned
  ++ is a record containing the value of the integral, the estimate of
  ++ the error in the computation, the total number of function
  ++ evaluations, and either a boolean value which is true if

characteristicPolynomial realEigenvalues realEigenvectors

— package NREP NumericRealEigenPackage —

```
)abbrev package NREP NumericRealEigenPackage
++ Author:P. Gianni
++ Date Created:Summer 1990
++ Date Last Updated:Spring 1991
++ Description:
++ This package computes explicitly eigenvalues and eigenvectors of
++ matrices with entries over the Rational Numbers.
++ The results are expressed as floating numbers or as rational numbers
```

++ depending on the type of the parameter Par.

NumericRealEigenPackage(Par) : C == T

where

Par : Join(Field,OrderedRing) -- Float or RationalNumber

SE ==> Symbol()

RN ==> Fraction Integer

I ==> Integer

NF ==> Float

CF ==> Complex Float

GRN ==> Complex RN

GI ==> Complex Integer

PI ==> PositiveInteger

NNI ==> NonNegativeInteger

MRN ==> Matrix RN

MPar ==> Matrix Par

outForm ==> Record(outval:Par,outmult:Integer,outvect>List MPar)

C == with

characteristicPolynomial : MRN -> Polynomial RN

++ characteristicPolynomial(m) returns the characteristic polynomial

++ of the matrix m expressed as polynomial

++ over RN with a new symbol as variable.

-- while the function in EigenPackage returns Fraction P RN.

characteristicPolynomial : (MRN,SE) -> Polynomial RN

++ characteristicPolynomial(m,x) returns the characteristic polynomial

++ of the matrix m expressed as polynomial

++ over RN with variable x.

-- while the function in EigenPackage returns

++ Fraction P RN.

realEigenvalues : (MRN,Par) -> List Par

++ realEigenvalues(m,eps) computes the eigenvalues of the matrix

++ m to precision eps. The eigenvalues are expressed as floats or

++ rational numbers depending on the type of eps (float or rational).

realEigenvectors : (MRN,Par) -> List(outForm)

++ realEigenvectors(m,eps) returns a list of

++ records each one containing

++ a real eigenvalue, its algebraic multiplicity, and a list of

++ associated eigenvectors. All these results

++ are computed to precision eps as floats or rational

++ numbers depending on the type of eps .

### — OpenMathServerPackage.help —

```
=====
OpenMathServerPackage examples
=====
```

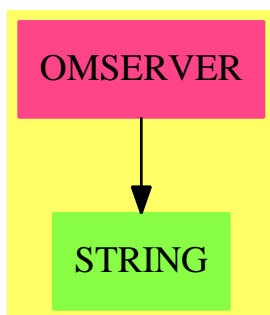

OpenMathServerPackage provides the necessary operations to run Axiom as an OpenMath server, reading/writing objects to/from a port. Please note the facilities available here are very basic. The idea is that a user calls e.g. `OMserve(4000,60)` and then another process sends

OpenMath objects to port 4000 and reads the result.

See Also:

o )show OpenMathServerPackage

## OpenMathServerPackage (OMSERVER)

### Exports:

output outputList

— package OUT OutputPackage —

```

)abbrev package OUT OutputPackage
++ Author: Stephen M. Watt
++ Date Created: February 1986
++ Date Last Updated: October 27 1995 (MCD)
++ Description:
++ OutPackage allows pretty-printing from programs.

OutputPackage: with

  output: String -> Void
    ++ output(s) displays the string s on the ‘‘algebra output’’
    ++ stream, as defined by \spadyscom{set output algebra}.

  output: OutputForm -> Void
    ++ output(x) displays the output form x on the
    ++ ‘‘algebra output’’ stream, as defined by
    ++ \spadyscom{set output algebra}.

  output: (String, OutputForm) -> Void
    ++ output(s,x) displays the string s followed by the form x
    ++ on the ‘‘algebra output’’ stream, as defined by
    ++ \spadyscom{set output algebra}.

  outputList: (List Any) -> Void
    ++ outputList(l) displays the concatenated components of the
    ++ list l on the ‘‘algebra output’’ stream, as defined by
    ++ \spadyscom{set output algebra}; quotes are stripped
    ++ from strings.

== add
  
```

```

  homogenize: (PolyRing,Integer) -> PolyRing

  interpolateFormsForFact: (DIVISOR,List PolyRing) -> List(PolyRing)

  fullDesTree: () -> Void

  fullInfClsPt: () -> Void

  setCurve: PolyRing -> PolyRing

  projectivePoint: List K -> ProjPt

  pointDominateBy : Plc -> ProjPt
    ++ pointDominateBy(pl) returns the projective point dominated
    ++ by the place pl.

  placesAbove: ProjPt -> List Plc

  setSingularPoints: List ProjPt -> List ProjPt

  goppaCode: (DIVISOR,DIVISOR) -> Matrix K

  goppaCode: (DIVISOR,List(Plc)) -> Matrix K

  rationalPlaces: () -> List Plc
    ++ rationalPlaces returns all the rational places of the
    ++ curve defined by the polynomial given to the package.

  theCurve: () -> PolyRing
    ++ theCurve returns the specified polynomial for the package.

  genus: () -> NNI
    ++ genus returns the genus of the curve defined by the polynomial
    ++ given to the package.

  genusNeg: () -> Integer

```

```

desingTreeWoFullParam : () -> List DesTree
  ++ desingTreeWoFullParam returns the desingularisation trees at all
  ++ singular points of the curve defined by the polynomial given to
  ++ the package. The local parametrizations are not computed.

desingTree: () -> List DesTree
  ++ desingTree returns the desingularisation trees at all singular
  ++ points of the curve defined by the polynomial given to the package.

rationalPoints: () -> List(ProjPt)

singularPoints: () -> List(ProjPt)
  ++ rationalPoints() returns the singular points of the
  ++ curve defined by the polynomial given to the package.
  ++ If the singular points lie in an extension of the specified
  ++ ground field an error message is issued specifying the extension
  ++ degree needed to find all singular points.

parametrize: (PolyRing,Plc) -> PCS
  ++ parametrize(f,pl) returns a local parametrization of f at the place pl.

lBasis: (DIVISOR,NNI) -> List FRACPOLY

lBasis: DIVISOR -> Record(num:List PolyRing, den: PolyRing)
  ++ lBasis computes a basis associated to the specified divisor

findOrderOfDivisor: (DIVISOR,Integer,Integer) -> _
  Record(ord:Integer,num:PolyRing,den:PolyRing,upTo:Integer)

interpolateForms: (DIVISOR,NNI) -> List(PolyRing)
  ++ interpolateForms(d,n) returns a basis of the interpolate forms of
  ++ degree n of the divisor d.

eval: (PolyRing,Plc) -> K
  ++ eval(f,pl) evaluate f at the place pl.

eval: (PolyRing,PolyRing,Plc) -> K
  ++ eval(f,g,pl) evaluate the function f/g at the place pl.

eval: (FRACPOLY,Plc) -> K
  ++ eval(u,pl) evaluate the function u at the place pl.

evalIfCan: (PolyRing,Plc) -> Union(K,"failed")
  ++ evalIfCan(f,pl) evaluate f at the place pl
  ++ (returns "failed" if it is a pole).

evalIfCan: (PolyRing,PolyRing,Plc) -> Union(K,"failed")
  ++ evalIfCan(f,g,pl) evaluate the function f/g at the place pl
  ++ (returns "failed" if it is a pole).

```

```

evalIfCan: (FRACPOLY,Plc) -> Union(K,"failed")
  ++ evalIfCan(u,pl) evaluate the function u at the place pl
  ++ (returns "failed" if it is a pole).

intersectionDivisor: PolyRing -> DIVISOR
  ++ intersectionDivisor(pol) compute the intersection divisor (the
  ++ Cartier divisor) of the form pol with the curve. If some
  ++ intersection points lie in an extension of the ground field,
  ++ an error message is issued specifying the extension degree
  ++ needed to find all the intersection points.
  ++ (If pol is not homogeneous an error message is issued).

adjunctionDivisor: () -> DIVISOR
  ++ adjunctionDivisor computes the adjunction divisor of the plane
  ++ curve given by the polynomial set with the function setCurve.

if K has Finite then --should we say LocallyAlgebraicallyClosedField??

LPolynomial: () -> SparseUnivariatePolynomial Integer
  ++ Returns the L-Polynomial of the curve.

LPolynomial: PI -> SparseUnivariatePolynomial Integer
  ++ LPolynomial(d) returns the L-Polynomial of the curve in
  ++ constant field extension of degree d.

classNumber: () -> Integer
  ++ Returns the class number of the curve.

placesOfDegree: PI -> List Plc
  ++ placesOfDegree(d) returns all places of degree d of the curve.

numberOfPlacesOfDegree: PI -> Integer
  ++ returns the number of places of the given degree

numberRatPlacesExtDeg: PI -> Integer
  ++ numberRatPlacesExtDeg(n) returns the number of rational
  ++ places in the constant field extension of degree n

numberPlacesDegExtDeg: (PI, PI) -> Integer
  ++ numberRatPlacesExtDegExtDeg(d, n) returns the number of
  ++ places of degree d in the constant field extension of degree n

ZetaFunction: () -> UTSZ
  ++ Returns the Zeta function of the curve. Calculated by
  ++ using the L-Polynomial

ZetaFunction: PI -> UTSZ
  ++ Returns the Zeta function of the curve in constant field
  ++ extension. Calculated by using the L-Polynomial

```

```

    goppaCode: (DIVISOR,List(Plc)) -> Matrix K

  pointDominateBy : Plc -> ProjPt
    ++ pointDominateBy(pl) returns the projective point dominated
    ++ by the place pl.

```

PACKAGE PAFFFF PACKAGEFORALGEBRAICFUNCTIONFIELDOVERFINITEFIELD3225

```
placesAbove: ProjPt -> List Plc

projectivePoint: List DK -> ProjPt

setSingularPoints: List ProjPt -> List ProjPt

rationalPlaces: () -> List Plc
  ++ rationalPlaces returns all the rational places of the
  ++ curve defined by the polynomial given to the package.

theCurve: () -> PolyRing
  ++ theCurve returns the specified polynomial for the package.

genus: () -> NNI
  ++ genus returns the genus of the curve defined by the polynomial
  ++ given to the package.

genusNeg: () -> Integer

desingTreeWoFullParam : () -> List DesTree
  ++ desingTreeWoFullParam returns the desingularisation trees at all
  ++ singular points of the curve defined by the polynomial given to
  ++ the package. The local parametrizations are not computed.

desingTree: () -> List DesTree
  ++ desingTree returns the desingularisation trees at all singular points
  ++ of the curve defined by the polynomial given to the package.

rationalPoints: () -> List(ProjPt)

singularPoints: () -> List(ProjPt)
  ++ rationalPoints() returns the singular points of the
  ++ curve defined by the polynomial given to the package.
  ++ If the singular points lie in an extension of the specified
  ++ ground field an error message is issued specifying the extension
  ++ degree needed to find all singular points.

parametrize: (PolyRing,Plc) -> PCS
  ++ parametrize(f,pl) returns a local parametrization of f at the place pl.

lBasis: (DIVISOR,NNI) -> List FracPoly

lBasis: DIVISOR -> Record(num:List PolyRing, den: PolyRing)
  ++ lBasis computes a basis associated to the specified divisor

findOrderOfDivisor: (DIVISOR,Integer,Integer) -> _
  Record(ord:Integer,num:PolyRing,den:PolyRing,upTo:Integer)

interpolateFormsForFact: (DIVISOR,List PolyRing) -> List(PolyRing2)
```

```

interpolateForms: (DIVISOR,NNI) -> List(PolyRing)
  ++ interpolateForms(d,n) returns a basis of the interpolate forms of
  ++ degree n of the divisor d.

eval: (PolyRing,Plc) -> K
  ++ eval(f,pl) evaluate f at the place pl.

eval: (PolyRing,PolyRing,Plc) -> K
  ++ eval(f,g,pl) evaluate the function f/g at the place pl.

eval: (FracPoly,Plc) -> K
  ++ eval(u,pl) evaluate the function u at the place pl.

evalIfCan: (PolyRing,Plc) -> Union(K,"failed")
  ++ evalIfCan(f,pl) evaluate f at the place pl
  ++ (returns "failed" if it is a pole).

evalIfCan: (PolyRing,PolyRing,Plc) -> Union(K,"failed")
  ++ evalIfCan(f,g,pl) evaluate the function f/g at the place pl
  ++ (returns "failed" if it is a pole).

evalIfCan: (FracPoly,Plc) -> Union(K,"failed")
  ++ evalIfCan(u,pl) evaluate the function u at the place pl
  ++ (returns "failed" if it is a pole).

intersectionDivisor: PolyRing -> DIVISOR
  ++ intersectionDivisor(pol) compute the intersection divisor of the
  ++ form pol with the curve.
  ++ (If pol is not homogeneous an error message is issued).

adjunctionDivisor: () -> DIVISOR
  ++ adjunctionDivisor computes the adjunction divisor of the plane
  ++ curve given by the polynomial defined by setCurve.

if DK has Finite then --should we say LocallyAlgebraicallyClosedField??

LPolynomial: () -> SparseUnivariatePolynomial Integer
  ++ Returns the L-Polynomial of the curve.

LPolynomial: PI -> SparseUnivariatePolynomial Integer
  ++ LPolynomial(d) returns the L-Polynomial of the curve in
++ constant field extension of degree d.

classNumber: () -> Integer
  ++ Returns the class number of the curve.

placesOfDegree: PI -> List Plc
  ++ placesOfDegree(d) returns all places of degree d of the
++ curve.

```

PACKAGE PAFFFF PACKAGEFORALGEBRAICFUNCTIONFIELDOVERFINITEFIELD3227

```
    numberOfPlacesOfDegree: PI -> Integer
      ++ returns the number of places of the given degree

    numberRatPlacesExtDeg: PI -> Integer
      ++ numberRatPlacesExtDeg(n) returns the number of rational
++ places in the constant field extension of degree n

    numberPlacesDegExtDeg: (PI, PI) -> Integer
      ++ numberRatPlacesExtDegExtDeg(d, n) returns the number of
++ places of degree d in the constant field extension of
++ degree n

    ZetaFunction: () -> UTSZ
      ++ Returns the Zeta function of the curve. Calculated by
++ using the L-Polynomial

    ZetaFunction: PI -> UTSZ
      ++ Returns the Zeta function of the curve in constant field
++ extension. Calculated by using the L-Polynomial

PAdicWildFunctionFieldIntegralBasis examples
=====

```

In this package  $K$  is a finite field,  $R$  is a ring of univariate polynomials over  $K$ , and  $F$  is a monogenic algebra over  $R$ .

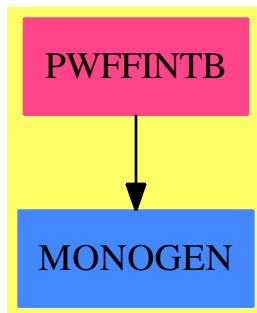

We require that  $F$  is monogenic, i.e. that  $F = K[x,y]/(f(x,y))$ , because the integral basis algorithm used will factor the polynomial  $f(x,y)$ . The package provides a function to compute the integral

closure of  $R$  in the quotient field of  $F$  as well as a function to compute a "local integral basis" at a specific prime.

ParametricLinearEquations examples
=====

```

This package completely solves a parametric linear system of equations by decomposing the set of all parametric values for which the linear system is consistent into a union of quasi-algebraic sets (which need not be irredundant, but most of the time is). Each quasi-algebraic set is described by a list of polynomials that vanish on the set, and a list of polynomials that vanish at no point of the set. For each quasi-algebraic set, the solution of the linear system is given, as a particular solution and a basis of the homogeneous system.

The parametric linear system should be given in matrix form, with a coefficient matrix and a right hand side vector. The entries of the coefficient matrix and right hand side vector should be polynomials in the parametric variables, over a Euclidean domain of characteristic zero.

If the system is homogeneous, the right hand side need not be given. The right hand side can also be replaced by an indeterminate vector, in which case, the conditions required for consistency will also be given.

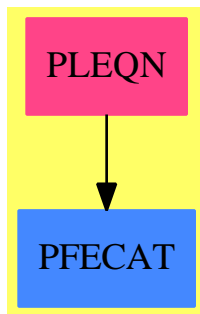

The package has other facilities for saving results to external files, as well as solving the system for a specified minimum rank. Altogether there are 12 mode maps for psolve, as explained below.

-- modified to conform with new runtime system 06/04/90
-- updated with comments for MB, 02/16/94
-- also cleaned up some unnecessary arguments in regime routine
--
-- MB: In order to allow the rhs to be indeterminate, while working
-- mainly with the parametric variables on the lhs (less number of
-- variables), certain conversions of internal representation from
-- GR to Polynomial R and Fraction Polynomial R are done. At the time
-- of implementation, I thought that this may be more efficient. I
-- have not done any comparison since that requires rewriting the
-- package. My own application needs to call this package quite often,
-- and most computations involves only polynomials in the parametric
-- variables.

-- The 12 modes of psolve are probably not all necessary. Again, I
-- was thinking that if there are many regimes and many ranks, then
-- the output is quite big, and it may be nice to be able to save it
-- and read the results in later to continue computing rather than
-- recomputing. Because of the combinatorial nature of the algorithm
-- (computing all subdeterminants!), it does not take a very big matrix
-- to get into many regimes. But I now have second thoughts of this
  
```

```
-- design, since most of the time, the results are just intermediate,
-- passed to be further processed. On the other hand, there is probably
-- no penalty in leaving the options as is.
```

— package PLEQN ParametricLinearEquations —

```
)abbrev package PLEQN ParametricLinearEquations
++ Author: William Sit, spring 89
++ Description:
++ This package completely solves a parametric linear system of equations
++ by decomposing the set of all parametric values for which the linear
++ system is consistent into a union of quasi-algebraic sets (which need
++ not be irredundant, but most of the time is). Each quasi-algebraic
++ set is described by a list of polynomials that vanish on the set, and
++ a list of polynomials that vanish at no point of the set.
++ For each quasi-algebraic set, the solution of the linear system
++ is given, as a particular solution and a basis of the homogeneous
++ system.
++
++ The parametric linear system should be given in matrix form, with
++ a coefficient matrix and a right hand side vector. The entries
++ of the coefficient matrix and right hand side vector should be
++ polynomials in the parametric variables, over a Euclidean domain
++ of characteristic zero.
++
++ If the system is homogeneous, the right hand side need not be given.
++ The right hand side can also be replaced by an indeterminate vector,
++ in which case, the conditions required for consistency will also be
++ given.
++
++ The package has other facilities for saving results to external
++ files, as well as solving the system for a specified minimum rank.
++ Altogether there are 12 mode maps for psolve, as explained below.

ParametricLinearEquations(R,Var,Expon,GR):
  Declaration == Definition where

  R      : Join(EuclideanDomain, CharacteristicZero)
  -- Warning: does not work if R is a field! because of Fraction R
  Var    : Join(OrderedSet,ConvertibleTo (Symbol))
  Expon  : OrderedAbelianMonoidSup
  GR     : PolynomialCategory(R,Expon,Var)
  F      == Fraction R

-- MB: The following macros are data structures to store mostly
-- intermediate results
-- Rec stores a subdeterminant with corresponding row and column indices
-- Fgb is a Groebner basis for the ideal generated by the subdeterminants
-- of a given rank.
-- Linsys specifies a linearly independent system of a given system
-- assuming a given rank, using given row and column indices
-- Linsoln stores the solution to the parametric linear system as a basis
-- and a particular solution (for a given regime)
-- Rec2 stores the rank, and a list of subdeterminants of that rank,
-- and a Groebner basis for the ideal they generate.
-- Rec3 stores a regime and the corresponding solution; the regime is
-- given by a list of equations (eqzro) and one inequation (neqzro)
-- describing the quasi-algebraic set which is the regime; the
-- additional consistency conditions due to the rhs is given by wcond.
-- Ranksolns stores a list of regimes and their solutions, and the number
-- of regimes all together.
-- Rec8 (temporary) stores a quasi-algebraic set with an indication
-- whether it is empty (sysok = false) or not (sysok = true).

-- I think psolve should be renamed parametricSolve, or even
-- parametricLinearSolve. On the other hand, may be just solve will do.
-- Please feel free to change it to conform with system conventions.
-- Most psolve routines return a list of regimes and solutions,
-- except those that output to file when the number of regimes is
-- returned instead.
-- This version has been tested on the pc version 1.608 March 13, 1992

++ number of regimes
-- this is mode 11
psolve: (M GR,          PI, S) -> I
++ psolve(c,k,s) solves  $c z = 0$  for all possible ranks  $\geq k$ 
++ of the matrix  $c$ ,
++ writes the results to a file named  $s$ , and returns the
++ number of regimes
-- this is mode 12

wrr regime : (L Rec3, S) -> I
++ wrr regime(l,s) writes a list of regimes to a file named  $s$ 
++ and returns the number of regimes written
rd regime : S -> L Rec3
++ rd regime(s) reads in a list from a file with name  $s$ 

-- for internal use only --
-- these are exported so my other packages can use them

bsolve: (M GR, L GF, NNI, S, Inputmode) -> Ranksolns
++ bsolve( $c, w, r, s, m$ ) returns a list of regimes and
++ solutions of the system  $c z = w$  for ranks at least  $r$ ;
++ depending on the mode  $m$  chosen, it writes the output to
++ a file given by the string  $s$ .
dmp2rfi: GR -> GF
++ dmp2rfi( $p$ ) converts  $p$  to target domain
dmp2rfi: M GR -> M GF
++ dmp2rfi( $m$ ) converts  $m$  to target domain
dmp2rfi: L GR -> L GF
++ dmp2rfi( $l$ ) converts  $l$  to target domain
se2rfi: L Symbol -> L GF
++ se2rfi( $l$ ) converts  $l$  to target domain
pr2dmp: PR -> GR
++ pr2dmp( $p$ ) converts  $p$  to target domain
hasoln: (Fgb, L GR) -> Rec8
++ hasoln( $g, l$ ) tests whether the quasi-algebraic set
++ defined by  $p = 0$  for  $p$  in  $g$  and  $q \hat{=} 0$  for  $q$  in  $l$ 
++ is empty or not and returns a simplified definition
++ of the quasi-algebraic set

```

```

-- this is now done in QALGSET package
ParCondList: (M GR,NNI) -> RankConds
  ++ ParCondList(c,r) computes a list of subdeterminants of each
  ++ rank >= r of the matrix c and returns
  ++ a groebner basis for the
  ++ ideal they generate
redpps: (Linsoln, Fgb) -> Linsoln
  ++ redpps(s,g) returns the simplified form of s after reducing
  ++ modulo a groebner basis g

```

-- LOCAL FUNCTIONS

```

Bisolve: Linsys -> Linsoln
  ++ Bisolve(s) solves the system (s.mat) z = s.vec
  ++ for the variables given by the column indices of s.cols
  ++ in terms of the other variables and the right hand side s.vec
  ++ by assuming that the rank is s.rank,
  ++ that the system is consistent, with the linearly
  ++ independent equations indexed by the given row indices s.rows;
  ++ the coefficients in s.mat involving parameters are treated as
  ++ polynomials. Bisolve(s) returns a particular solution to the
  ++ system and a basis of the homogeneous system (s.mat) z = 0.
factorset: GR -> L GR
  ++ factorset(p) returns the set of irreducible factors of p.
maxrank: RankConds -> NNI
  ++ maxrank(r) returns the maximum rank in the list r of regimes
minrank: RankConds -> NNI
  ++ minrank(r) returns the minimum rank in the list r of regimes
minset: L L GR -> L L GR
  ++ minset(sl) returns the sublist of sl consisting of the minimal
  ++ lists (with respect to inclusion) in the list sl of lists
nextSublist: (I, I) -> L L I
  ++ nextSublist(n,k) returns a list of k-subsets of {1, ..., n}.
overset?: (L GR, L L GR) -> Boolean
  ++ overset?(s,sl) returns true if s properly a sublist of a member
  ++ of sl; otherwise it returns false
ParCond : (M GR,NNI) -> Eqns
  ++ ParCond(m,k) returns the list of all k by k subdeterminants in
  ++ the matrix m
redmat: (M GR, Fgb) -> M GR
  ++ redmat(m,g) returns a matrix whose entries are those of m
  ++ modulo the ideal generated by the groebner basis g
regime: (Rec,M GR,L GF,L L GR,NNI,NNI,Inputmode) -> Rec3
  ++ regime(y,c, w, p, r, rm, m) returns a regime,
  ++ a list of polynomials specifying the consistency conditions,
  ++ a particular solution and basis representing the general
  ++ solution of the parametric linear system c z = w
  ++ on that regime. The regime returned depends on

```

```

++ the subdeterminant y.det and the row and column indices.
++ The solutions are simplified using the assumption that
++ the system has rank r and maximum rank rm. The list p
++ represents a list of list of factors of polynomials in
++ a groebner basis of the ideal generated by higher order
++ subdeterminants, and ius used for the simplification.
++ The mode m
++ distinguishes the cases when the system is homogeneous,
++ or the right hand side is arbitrary, or when there is no
++ new right hand side variables.
sqfree: GR -> GR
++ sqfree(p) returns the product of square free factors of p
inconsistent?: L GR -> Boolean
++ inconsistant?(pl) returns true if the system of equations
++ p = 0 for p in pl is inconsistent. It is assumed
++ that pl is a groebner basis.
-- this is needed because of change to
-- EuclideanGroebnerBasisPackage
inconsistent?: L PR -> Boolean
++ inconsistant?(pl) returns true if the system of equations
++ p = 0 for p in pl is inconsistent. It is assumed
++ that pl is a groebner basis.
-- this is needed because of change to
-- EuclideanGroebnerBasisPackage

— PartialFractionPackage.help —

=====  
PartialFractionPackage examples  
=====

The package PartialFractionPackage gives an easier to use interface to the domain PartialFraction. The user gives a fraction of polynomials, and a variable and the package converts it to the proper datatype for the PartialFraction domain.

When Axiom is given an expression such as:

a:=x+1/(y+1)

it will end up with the result in Fraction Polynomial Integer.

$$\frac{xy + x + 1}{y + 1}$$

We might want it in a partial fraction form. This can be done with:

partialFraction(a,y)\$PFRPAC(INT)

$$x + \frac{1}{y + 1}$$

We can do the same thing with a different variable:

b:=y+1/(x+1)

$$\frac{(x + 1)y + 1}{x + 1}$$

partialFraction(b,x)\$PFRPAC(INT)

$$y + \frac{1}{x + 1}$$

## PartitionsAndPermutations (PARTPERM)

**Exports:**

conjugate conjugates partitions permutations sequences  
 shuffle shufflein

— package PARTPERM PartitionsAndPermutations —

```

)abbrev package PARTPERM PartitionsAndPermutations
++ Author: William H. Burge
++ Date Created: 29 October 1987
++ Date Last Updated: 3 April 1991
++ Description:
++ PartitionsAndPermutations contains functions for generating streams of
++ integer partitions, and streams of sequences of integers
++ composed from a multi-set.
  
```

PartitionsAndPermutations: Exports == Implementation where

```

I ==> Integer
L ==> List
ST ==> Stream
ST1 ==> StreamFunctions1
ST2 ==> StreamFunctions2
ST3 ==> StreamFunctions3
  
```

Exports ==> with

```

partitions: (I,I,I) -> ST L I
  ++\spad{partitions(p,l,n)} is the stream of partitions
  ++ of n whose number of parts is no greater than p
  ++ and whose largest part is no greater than l.
partitions: I -> ST L I
  ++\spad{partitions(n)} is the stream of all partitions of n.
partitions: (I,I) -> ST L I
  ++\spad{partitions(p,l)} is the stream of all
  ++ partitions whose number of
  ++ parts and largest part are no greater than p and l.
  
```

```

conjugate: L I -> L I
  ++\spad{conjugate(pt)} is the conjugate of the partition pt.
conjugates: ST L I -> ST L I
  ++\spad{conjugates(lp)} is the stream of conjugates of a stream
  ++ of partitions lp.
shuffle: (L I,L I) -> ST L I
  ++\spad{shuffle(l1,l2)} forms the stream of all shuffles of l1
  ++ and l2, i.e. all sequences that can be formed from
  ++ merging l1 and l2.
shufflein: (L I,ST L I) -> ST L I
  ++\spad{shufflein(l,st)} maps shuffle(l,u) on to all
  ++ members u of st, concatenating the results.
sequences: (L I,L I) -> ST L I
  ++\spad{sequences(l1,l2)} is the stream of all sequences that
  ++ can be composed from the multiset defined from
  ++ two lists of integers l1 and l2.
  ++ For example,the pair \spad{([1,2,4],[2,3,5])} represents
  ++ multi-set with 1 \spad{2}, 2 \spad{3}'s, and 4 \spad{5}'s.
sequences: L I -> ST L I
  ++ \spad{sequences([l0,l1,l2,..,ln])} is the set of
  ++ all sequences formed from
  ++ \spad{l0} 0's,\spad{l1} 1's,\spad{l2} 2's,...,\spad{ln} n's.
permutations: I -> ST L I
  ++\spad{permutations(n)} is the stream of permutations
  ++ formed from \spad{1,2,3,...,n}.

```

Implementation ==> add

```

partitions(M,N,n) ==
  zero? n => concat(empty()$L(I),empty()$(ST L I))
  zero? M or zero? N or n < 0 => empty()
  c := map((l1>List(I)):List(I)+->concat(N,l1),partitions(M - 1,N,n - N))
  concat(c,partitions(M,N - 1,n))

partitions n == partitions(n,n,n)

partitions(M,N)==
  aaa : L ST L I := [partitions(M,N,i) for i in 0..M*N]
  concat(aaa :: ST ST L I)$ST1(L I)

-- nogreq(n,l) is the number of elements of l that are greater or
-- equal to n
nogreq: (I,L I) -> I
nogreq(n,x) == +/[1 for i in x | i >= n]

conjugate x ==
  empty? x => empty()
  [nogreq(i,x) for i in 1..first x]

conjugates z == map(conjugate,z)

```

```

shuffle(x,y)==
  empty? x => concat(y,empty())$(ST L I)
  empty? y => concat(x,empty())$(ST L I)
  concat(map((l1>List(I)):List(I)+->concat(first x,l1),shuffle(rest x,y)),_
    map((l2>List(I)):List(I)+->concat(first y,l2),shuffle(x,rest y)))

shufflein(x,yy) ==
  concat(map((l1>List(I)):ST(L I)+->shuffle(x,l1),yy)_
    $ST2(L I,ST L I))$ST1(L I)

-- rpt(n,m) is the list of n m's
rpt: (I,I) -> L I
rpt(n,m) == [m for i in 1..n]

-- zrpt(x,y) where x is [x0,x1,x2...] and y is [y0,y1,y2...]
-- is the stream [rpt(x0,y0),rpt(x1,y1),...]
zrpt: (L I,L I) -> ST L I
zrpt(x,y) == map(rpt,x :: ST I,y :: ST I)$ST3(I,I,L I)

sequences(x,y) ==
  reduce(concat(empty()$L(I),empty()$(ST L I)),_
    shufflein,zrpt(x,y))$ST2(L I,ST L I)

sequences x == sequences(x,[i for i in 0..#x-1])

permutations n == sequences(rpt(n,1),[i for i in 1..n])

=====
Permanent examples
=====

```

The package Permanent provides the function permanent for square matrices. The permanent of a square matrix can be computed in the same way as the determinant by expansion of minors except that for the permanent the sign for each element is 1, rather than being 1 if the row plus column indices is positive and -1 otherwise. This function is much more difficult to compute efficiently than the determinant. An example of the use of permanent is the calculation of the n-th derangement number, defined to be the number of different possibilities for n couples to dance but never with their own spouse.

Consider an n by n matrix with entries 0 on the diagonal and 1 elsewhere. Think of the rows as one-half of each couple (for example, the males) and the columns the other half. The permanent of such a matrix gives the desired derangement number.

```

kn n ==
  r : MATRIX INT := new(n,n,1)
  for i in 1..n repeat
    r.i.i := 0
  r

```

Here are some derangement numbers, which you see grow quite fast.

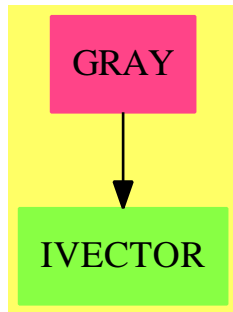

```
permanent(kn(5) :: SQMATRIX(5,INT))
[permanent(kn(n) :: SQMATRIX(n,INT)) for n in 1..13]
```

  SM ==> SquareMatrix(n,R)
  VECTPKG1 ==> VectorPackage1(I)
  NNI ==> NonNegativeInteger
  PI ==> PositiveInteger
  GRAY ==> GrayCode

public ==> with

  permanent: SM -> R
    ++ permanent(x) computes the permanent of a square matrix x.
    ++ The permanent is equivalent to
    ++ the \spadfun{determinant} except that coefficients have
    ++ no change of sign. This function
    ++ is much more difficult to compute than the
    ++ determinant. The formula used is by H.J. Ryser,
    ++ improved by [Nijenhuis and Wilf, Ch. 19].
    ++ Note that permanent(x) choose one of three algorithms, depending
    ++ on the underlying ring R and on n, the number of rows (and
    ++ columns) of x:\br
    ++ if 2 has an inverse in R we can use the algorithm of
    ++ [Nijenhuis and Wilf, ch.19,p.158]; if 2 has no inverse,
    ++ some modifications are necessary:\br
    ++ if n > 6 and R is an integral domain with characteristic
    ++ different from 2 (the algorithm works if and only 2 is not a
    ++ zero-divisor of R and characteristic()$R ^= 2,
    ++ but how to check that for any given R ?),
    ++ the local function permanent2 is called;\br
    ++ else, the local function permanent3 is called
    ++ (works for all commutative rings R).

++ integers given in the list li.
++ Note that duplicates in the list will be removed.
++ Error: if li has less or more than 23 different entries.
mathieu23:      ()      -> PERMGRP I
++ mathieu23 constructs the mathieu group acting on the
++ integers 1,...,23.
mathieu24:      L I      -> PERMGRP I
++ mathieu24(li) constructs the mathieu group acting on the 24
++ integers given in the list li.
++ Note that duplicates in the list will be removed.
++ Error: if li has less or more than 24 different entries.
mathieu24:      ()      -> PERMGRP I
++ mathieu24 constructs the mathieu group acting on the
++ integers 1,...,24.
janko2:        L I      -> PERMGRP I
++ janko2(li) constructs the janko group acting on the 100
++ integers given in the list li.
++ Note that duplicates in the list will be removed.
++ Error: if li has less or more than 100 different entries
janko2:        ()      -> PERMGRP I
++ janko2 constructs the janko group acting on the
++ integers 1,...,100.
rubiksGroup:   ()      -> PERMGRP I
++ rubiksGroup constructs the permutation group representing
++ Rubic's Cube acting on integers 10*i+j for
++ 1 <= i <= 6, 1 <= j <= 8.
++ The faces of Rubik's Cube are labelled in the obvious way
++ Front, Right, Up, Down, Left, Back and numbered from 1 to 6
++ in this given ordering, the pieces on each face
++ (except the unmoveable center piece) are clockwise numbered

```

```

++ from 1 to 8 starting with the piece in the upper left
++ corner. The moves of the cube are represented as permutations
++ on these pieces, represented as a two digit
++ integer ij where i is the numer of theface (1 to 6)
++ and j is the number of the piece on this face.
++ The remaining ambiguities are resolved by looking
++ at the 6 generators, which represent a 90 degree turns of the
++ faces, or from the following pictorial description.
++ Permutation group representing Rubic's Cube acting on integers
++ 10*i+j for 1 <= i <= 6, 1 <= j <=8.
++
++ \begin{verbatim}
++ Rubik's Cube:  +-----+ +--- B   where: marks Side # :
++                / U   //
++                /   / |       F(ront)   <->   1
++      L  -->  +-----+ R|       R(ight)   <->   2
++                |   | +       U(p)       <->   3
++                | F | /       D(own)     <->   4
++                |   | /       L(eft)     <->   5
++                +-----+     B(ack)     <->   6
++                ^
++                |
++                D
++
++ The Cube's surface:
++
++                +----+
++                |567|
++                |4U8|
++                |321|
++                +----+-----+
++                |781|123|345|
++                |6L2|8F4|2R6|
++                |543|765|187|
++                +----+-----+

**Exports:**

algebraicSet rationalPoints singularPoints singularPointsWithRestriction

— package PRJALGPK ProjectiveAlgebraicSetPackage —

```

)abbrev package PRJALGPK ProjectiveAlgebraicSetPackage
++ Author: Gaetan Hache
++ Date Created: 17 nov 1992
++ Date Last Updated: May 2010 by Tim Daly
++ Description:
++ The following is part of the PAFF package
ProjectiveAlgebraicSetPackage(K,symb,PolyRing,E,ProjPt):_
Exports == Implementation where
  K      : Field
  symb: List(Symbol)
  OV ==> OrderedVariableList(symb)
  E : DirectProductCategory(#symb,NonNegativeInteger)
  PolyRing : PolynomialCategory(K,E,OV)
  ProjPt   : ProjectiveSpaceCategory(K)
  PCS      : LocalPowerSeriesCategory(K)

  OF ==> OutputForm
  PI ==> PositiveInteger
  RFP ==> RootsFindingPackage
  SUP ==> SparseUnivariatePolynomial
  PPFC1 ==> PolynomialPackageForCurve(K,PolyRing,E,#symb,ProjPt)
  SPWRES ==> AffineAlgebraicSetComputeWithResultant(K,symb,PolyRing,E,ProjPt)
  SPWGRO ==> AffineAlgebraicSetComputeWithGroebnerBasis(K,symb,PolyRing,E,ProjPt)

Exports ==> with

  singularPointsWithRestriction: (PolyRing,List(PolyRing)) -> List(ProjPt)
    ++ return the singular points that anihilate

  singularPoints: PolyRing -> List(ProjPt)
    ++ singularPoints retourne les points singulier

  algebraicSet: List(PolyRing) -> List(ProjPt)
    ++ algebraicSet returns the algebraic set if finite (dimension 0).

  rationalPoints: (PolyRing,PI) -> List(ProjPt)
    ++ \axiom{rationalPoints(f,d)} returns all points on the curve \axiom{f}
    ++ in the extension of the ground field of degree \axiom{d}.
    ++ For \axiom{d > 1} this only works if \axiom{K} is a
    ++ \axiomType{LocallyAlgebraicallyClosedField}

Implementation ==> add

=====
PolyGroebner examples
=====

```

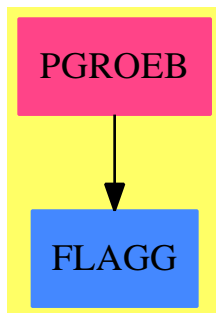

This package is an interface package to the groebner basis package which allows you to compute groebner bases for polynomials in either lexicographic ordering or total degree ordering refined by reverse lex. The input is the ordinary polynomial type which is internally converted to a type with the required ordering. The resulting grobner basis is converted back to ordinary polynomials. The ordering among the variables is controlled by an explicit list of variables which is passed as a second argument. The coefficient

domain is allowed to be any gcd domain, but the groebner basis is computed as if the polynomials were over a field.

### Exports:

lexGroebner totalGroebner

— package PGROEB PolyGroebner —

```

)abbrev package PGROEB PolyGroebner
++ Author: P. Gianni
++ Date Created: Summer 1988
++ Description:
++ Groebner functions for P F
++ This package is an interface package to the groebner basis
++ package which allows you to compute groebner bases for polynomials
++ in either lexicographic ordering or total degree ordering refined
++ by reverse lex. The input is the ordinary polynomial type which
++ is internally converted to a type with the required ordering.
++ The resulting grobner basis is converted back to ordinary polynomials.
++ The ordering among the variables is controlled by an explicit list
++ of variables which is passed as a second argument. The coefficient
++ domain is allowed to be any gcd domain, but the groebner basis is
++ computed as if the polynomials were over a field.
  
```

PolyGroebner(F) : C == T

```

where
  F      : GcdDomain

PolynomialFactorizationByRecursionUnivariate

R is a PolynomialFactorizationExplicit domain,

S is univariate polynomials over R

We are interested in handling SparseUnivariatePolynomials over

S, is a variable we shall call z

## PolynomialGcdPackage (PGCD)

### Exports:

gcd gcdPrimitive

The simple Euclidean division algorithm,

**given**  $a \neq 0, b \neq 0$  where  $a$  and  $b$  are two polynomials in the variable  $x$ , then

**output**  $q$ , the quotient and  $r$ , the remainder

**begin**

**Let**

$q = 0$

$r = a$

$d = \text{degree}(b)$

$c = \text{leadingCoefficient}(b)$

**while**  $\text{degree}(r) \geq d$  **do**

$e = \text{degree}(r) - d$

$s = \frac{\text{leadingCoefficient}(r)}{c} x^e$

$q = q + s$

$r = r - sb$

**endwhile**

**return**( $q,r$ )

**end**

For example, given

$p1 := (x+1) * (x+6)$

$p2 := (x+1) * (x-6)$

$\text{gcd}(p1,p2) \rightarrow x+1$

In Gathen [Gath99] we find a discussion of applying the Euclidean algorithm to elements of a field. In a field every nonzero rational number is a unit. If we want to define a single element such that

$$\gcd(f, g) \in \mathbf{Q}[x]$$

we choose a monic polynomial, that is, the element with a leading coefficient of 1. So

$$\text{abs}(a / \text{leadingCoefficient}(a))$$

defines a normal form of  $a$ .

Gathen also notes that for polynomials we should modify the Euclidean algorithm so *all* remainders are normalized. Without this constraint the remainders will have huge numerators and denominators.

```

Hensel's lifting lemma states that if a polynomial equation has a simple root modulo a prime number  $p$ , then this root corresponds to a unique root of the same equation modulo any higher power of  $p$ , which can be found by iteratively "lifting" the solution modulo successive powers of  $p$ .

See Volume 10.1 for more details.

— package PNTHEORY PolynomialNumberTheoryFunctions —

```
)abbrev package PNTHEORY PolynomialNumberTheoryFunctions
++ Author: Michael Monagan, Clifton J. Williamson
++ Date Created: June 1987
++ Date Last Updated: 10 November 1996 (Claude Quitte)
++ References: Knuth, The Art of Computer Programming Vol.2
++ Description:
++ This package provides various polynomial number theoretic functions
++ over the integers.
```

```
PolynomialNumberTheoryFunctions(): Exports == Implementation where
I ==> Integer
RN ==> Fraction I
SUP ==> SparseUnivariatePolynomial
NNI ==> NonNegativeInteger
```

```

Exports ==> with
bernoulli : I -> SUP RN
  ++ bernoulli(n) returns the nth Bernoulli polynomial \spad{B[n](x)}.
  ++ Bernoulli polynomials denoted \spad{B(n,x)} computed by solving the
  ++ differential equation \spad{differentiate(B(n,x),x) = n B(n-1,x)} where
  ++ \spad{B(0,x) = 1} and initial condition comes from \spad{B(n) = B(n,0)}.
chebyshevT: I -> SUP I
  ++ chebyshevT(n) returns the nth Chebyshev polynomial \spad{T[n](x)}.
  ++ Note that Chebyshev polynomials of the first kind,
  ++ denoted \spad{T[n](x)},
  ++ computed from the two term recurrence. The generating function
  ++ \spad{(1-t*x)/(1-2*t*x+t**2) = sum(T[n](x)*t**n, n=0..infinity)}.
chebyshevU: I -> SUP I
  ++ chebyshevU(n) returns the nth Chebyshev polynomial \spad{U[n](x)}.
  ++ Note that Chebyshev polynomials of the second kind,
  ++ denoted \spad{U[n](x)},
  ++ computed from the two term recurrence. The generating function
  ++ \spad{1/(1-2*t*x+t**2) = sum(T[n](x)*t**n, n=0..infinity)}.
cyclotomic: I -> SUP I
  ++ cyclotomic(n) returns the nth cyclotomic polynomial \spad{phi[n](x)}.
  ++ Note that \spad{phi[n](x)} is the factor of \spad{x**n - 1} whose roots
  ++ are the primitive nth roots of unity.
euler : I -> SUP RN
  ++ euler(n) returns the nth Euler polynomial \spad{E[n](x)}.
  ++ Note that Euler polynomials denoted \spad{E(n,x)} computed by solving
  ++ the differential equation
  ++ \spad{differentiate(E(n,x),x) = n E(n-1,x)} where
  ++ \spad{E(0,x) = 1} and initial condition comes
  ++ from \spad{E(n) = 2**n E(n,1/2)}.
fixedDivisor: SUP I -> I
  ++ fixedDivisor(a) for \spad{a(x)} in \spad{Z[x]} is the largest integer
  ++ f such that f divides \spad{a(x=k)} for all integers k.
  ++ Note that fixed divisor of \spad{a} is
  ++ \spad{reduce(gcd,[a(x=k) for k in 0..degree(a)])}.
hermite : I -> SUP I
  ++ hermite(n) returns the nth Hermite polynomial \spad{H[n](x)}.
  ++ Note that Hermite polynomials, denoted \spad{H[n](x)}, are computed from
  ++ the two term recurrence. The generating function is:
  ++ \spad{exp(2*t*x-t**2) = sum(H[n](x)*t**n/n!, n=0..infinity)}.
laguerre : I -> SUP I
  ++ laguerre(n) returns the nth Laguerre polynomial \spad{L[n](x)}.
  ++ Note that Laguerre polynomials, denoted \spad{L[n](x)}, are computed
  ++ from the two term recurrence. The generating function is:
  ++ \spad{exp(x*t/(t-1))/(1-t) = sum(L[n](x)*t**n/n!, n=0..infinity)}.
legendre : I -> SUP RN
  ++ legendre(n) returns the nth Legendre polynomial \spad{P[n](x)}.
  ++ Note that Legendre polynomials, denoted \spad{P[n](x)}, are computed
  ++ from the two term recurrence. The generating function is:
  ++ \spad{1/sqrt(1-2*t*x+t**2) = sum(P[n](x)*t**n, n=0..infinity)}.

```

```

— package PSETPK PolynomialSetUtilitiesPackage —

```

)abbrev package PSETPK PolynomialSetUtilitiesPackage
++ Author: Marc Moreno Maza (marc@nag.co.uk)
++ Date Created: 12/01/1995
++ Date Last Updated: 12/15/1998
++ Description:
++ This package provides modest routines for polynomial system solving.
++ The aim of many of the operations of this package is to remove certain
++ factors in some polynomials in order to avoid unnecessary computations
++ in algorithms involving splitting techniques by partial factorization.
  
```

removeRedundantFactors: LP -> LP
++ \axiom{removeRedundantFactors(lp)} returns \axiom{lq} such that if
++ \axiom{lp = [p1,...,pn]} and \axiom{lq = [q1,...,qm]}
++ then the product \axiom{p1*p2*...*pn} vanishes iff the product \axiom{q1*q2*...*qm} v
++ and the product of the degrees of the \axiom{qi} is not greater than
++ the one of the \axiom{pj}, and no polynomial in \axiom{lq}
++ divides another polynomial in \axiom{lq}. In particular,
++ polynomials lying in the base ring \axiom{R} are removed.
++ Moreover, \axiom{lq} is sorted w.r.t \axiom{infRittWu?}.
++ Furthermore, if R is gcd-domain, the polynomials in \axiom{lq} are
++ pairwise without common non trivial factor.
removeRedundantFactors: (P,P) -> LP
++ \axiom{removeRedundantFactors(p,q)} returns the same as
++ \axiom{removeRedundantFactors([p,q])}
removeSquaresIfCan : LP -> LP
++ \axiom{removeSquaresIfCan(lp)} returns
++ \axiom{removeDuplicates [squareFreePart(p)$P for p in lp]}
++ if \axiom{R} is gcd-domain else returns \axiom{lp}.
unprotectedRemoveRedundantFactors: (P,P) -> LP
++ \axiom{unprotectedRemoveRedundantFactors(p,q)} returns the same as
++ \axiom{removeRedundantFactors(p,q)} but does assume that neither
++ \axiom{p} nor \axiom{q} lie in the base ring \axiom{R} and assumes that
++ \axiom{infRittWu?(p,q)} holds. Moreover, if \axiom{R} is gcd-domain,
++ then \axiom{p} and \axiom{q} are assumed to be square free.
removeRedundantFactors: (LP,P) -> LP
++ \axiom{removeRedundantFactors(lp,q)} returns the same as
++ \axiom{removeRedundantFactors(cons(q,lp))} assuming
++ that \axiom{removeRedundantFactors(lp)} returns \axiom{lp}
++ up to replacing some polynomial \axiom{pj} in \axiom{lp}
++ by some some polynomial \axiom{qj} associated to \axiom{pj}.

```

```

removeRedundantFactors : (LP,LP) -> LP
  ++ \axiom{removeRedundantFactors(lp,lq)} returns the same as
  ++ \axiom{removeRedundantFactors(concat(lp,lq))} assuming
  ++ that \axiom{removeRedundantFactors(lp)} returns \axiom{lp}
  ++ up to replacing some polynomial \axiom{pj} in \axiom{lp}
  ++ by some polynomial \axiom{qj} associated to \axiom{pj}.
removeRedundantFactors : (LP,LP,(LP -> LP)) -> LP
  ++ \axiom{removeRedundantFactors(lp,lq,remOp)} returns the same as
  ++ \axiom{concat(remOp(removeRoughlyRedundantFactorsInPols(lp,lq)),lq)}
  ++ assuming that \axiom{remOp(lq)} returns \axiom{lq} up to similarity.
certainlySubVariety? : (LP,LP) -> B
  ++ \axiom{certainlySubVariety?(newlp,lp)} returns true iff for every \axiom{p}
  ++ in \axiom{lp} the remainder of \axiom{p} by \axiom{newlp} using the division algorithm
  ++ of Groebner techniques is zero.
possiblyNewVariety? : (LP, List LP) -> B
  ++ \axiom{possiblyNewVariety?(newlp,llp)} returns true iff for every \axiom{lp}
  ++ in \axiom{llp} certainlySubVariety?(newlp,lp) does not hold.
probablyZeroDim?: LP -> B
  ++ \axiom{probablyZeroDim?(lp)} returns true iff the number of polynomials
  ++ in \axiom{lp} is not smaller than the number of variables occurring
  ++ in these polynomials.
selectPolynomials : ((P -> B),LP) -> Record(goodPols:LP,badPols:LP)
  ++ \axiom{selectPolynomials(pred?,ps)} returns \axiom{gps,bps} where
  ++ \axiom{gps} is a list of the polynomial \axiom{p} in \axiom{ps}
  ++ such that \axiom{pred?(p)} holds and \axiom{bps} are the other ones.
selectOrPolynomials : (List (P -> B),LP) -> Record(goodPols:LP,badPols:LP)
  ++ \axiom{selectOrPolynomials(lpred?,ps)} returns \axiom{gps,bps} where
  ++ \axiom{gps} is a list of the polynomial \axiom{p} in \axiom{ps}
  ++ such that \axiom{pred?(p)} holds for some \axiom{pred?} in \axiom{lpred?}
  ++ and \axiom{bps} are the other ones.
selectAndPolynomials : (List (P -> B),LP) -> Record(goodPols:LP,badPols:LP)
  ++ \axiom{selectAndPolynomials(lpred?,ps)} returns \axiom{gps,bps} where
  ++ \axiom{gps} is a list of the polynomial \axiom{p} in \axiom{ps}
  ++ such that \axiom{pred?(p)} holds for every \axiom{pred?} in \axiom{lpred?}
  ++ and \axiom{bps} are the other ones.
quasiMonicPolynomials : LP -> Record(goodPols:LP,badPols:LP)
  ++ \axiom{quasiMonicPolynomials(lp)} returns \axiom{qmmps,nqmmps} where
  ++ \axiom{qmmps} is a list of the quasi-monic polynomials in \axiom{lp}
  ++ and \axiom{nqmmps} are the other ones.
univariate? : P -> B
  ++ \axiom{univariate?(p)} returns true iff \axiom{p} involves one and
  ++ only one variable.
univariatePolynomials : LP -> Record(goodPols:LP,badPols:LP)
  ++ \axiom{univariatePolynomials(lp)} returns \axiom{ups,nups} where
  ++ \axiom{ups} is a list of the univariate polynomials,
  ++ and \axiom{nups} are the other ones.
linear? : P -> B
  ++ \axiom{linear?(p)} returns true iff \axiom{p} does not lie
  ++ in the base ring \axiom{R} and has main degree \axiom{1}.
linearPolynomials : LP -> Record(goodPols:LP,badPols:LP)

```

```

++ \axiom{linearPolynomials(lp)} returns \axiom{lps,nlps} where
++ \axiom{lps} is a list of the linear polynomials in lp,
++ and \axiom{nlps} are the other ones.
bivariate? : P -> B
++ \axiom{bivariate?(p)} returns true iff \axiom{p} involves two and
++ only two variables.
bivariatePolynomials : LP -> Record(goodPols:LP,badPols:LP)
++ \axiom{bivariatePolynomials(lp)} returns \axiom{bps,nbps} where
++ \axiom{bps} is a list of the bivariate polynomials,
++ and \axiom{nbps} are the other ones.
removeRoughlyRedundantFactorsInPols : (LP, LP) -> LP
++ \axiom{removeRoughlyRedundantFactorsInPols(lp,lf)} returns
++ \axiom{newlp} where \axiom{newlp} is obtained from \axiom{lp}
++ by removing in every polynomial \axiom{p} of \axiom{lf}
++ any occurrence of a polynomial \axiom{f} in \axiom{lf}.
++ This may involve a lot of exact-quotients computations.
removeRoughlyRedundantFactorsInPols : (LP, LP,B) -> LP
++ \axiom{removeRoughlyRedundantFactorsInPols(lp,lf,opt)} returns
++ the same as \axiom{removeRoughlyRedundantFactorsInPols(lp,lf)}
++ if \axiom{opt} is \axiom{false} and if the previous operation
++ does not return any non null and constant polynomial,
++ else return \axiom{[1]}.
removeRoughlyRedundantFactorsInPol : (P,LP) -> P
++ \axiom{removeRoughlyRedundantFactorsInPol(p,lf)} returns the same as
++ removeRoughlyRedundantFactorsInPols([p],lf,true)
interReduce: LP -> LP
++ \axiom{interReduce(lp)} returns \axiom{lq} such that \axiom{lp}
++ and \axiom{lq} generate the same ideal and no polynomial
++ in \axiom{lq} is reducible by the others in the sense
++ of Groebner bases. Since no assumptions are required
++ the result may depend on the ordering the reductions are
++ performed.
roughBasicSet: LP -> Union(Record(bas:T,top:LP),"failed")
++ \axiom{roughBasicSet(lp)} returns the smallest (with Ritt-Wu
++ ordering) triangular set contained in \axiom{lp}.
crushedSet: LP -> LP
++ \axiom{crushedSet(lp)} returns \axiom{lq} such that \axiom{lp} and
++ and \axiom{lq} generate the same ideal and no rough basic
++ sets reduce (in the sense of Groebner bases) the other
++ polynomials in \axiom{lq}.
rewriteSetByReducingWithParticularGenerators : (LP,(P->B),((P,P)->B),((P,P)->P)) -> LP
++ \axiom{rewriteSetByReducingWithParticularGenerators(lp,pred?,redOp?,redOp)}
++ returns \axiom{lq} where \axiom{lq} is computed by the following
++ algorithm. Chose a basic set w.r.t. the reduction-test \axiom{redOp?}
++ among the polynomials satisfying property \axiom{pred?},
++ if it is empty then leave, else reduce the other polynomials by
++ this basic set w.r.t. the reduction-operation \axiom{redOp}.
++ Repeat while another basic set with smaller rank can be computed.
++ See code. If \axiom{pred?} is \axiom{quasiMonic?} the ideal is unchanged.
rewriteIdealWithQuasiMonicGenerators : (LP,((P,P)->B),((P,P)->P)) -> LP

```

```

++ \axiom{rewriteIdealWithQuasiMonicGenerators(lp,redOp?,redOp)} returns
++ \axiom{lq} where \axiom{lq} and \axiom{lp} generate
++ the same ideal in \axiom{R(-1) P} and \axiom{lq}
++ has rank not higher than the one of \axiom{lp}.
++ Moreover, \axiom{lq} is computed by reducing \axiom{lp}
++ w.r.t. some basic set of the ideal generated by
++ the quasi-monic polynomials in \axiom{lp}.
if R has GcdDomain
then
squareFreeFactors : P -> LP
++ \axiom{squareFreeFactors(p)} returns the square-free factors of \axiom{p}
++ over \axiom{R}
univariatePolynomialsGcds : LP -> LP
++ \axiom{univariatePolynomialsGcds(lp)} returns \axiom{lg} where
++ \axiom{lg} is a list of the gcds of every pair in \axiom{lp}
++ of univariate polynomials in the same main variable.
univariatePolynomialsGcds : (LP,B) -> LP
++ \axiom{univariatePolynomialsGcds(lp,opt)} returns the same as
++ \axiom{univariatePolynomialsGcds(lp)} if \axiom{opt} is
++ \axiom{false} and if the previous operation does not return
++ any non null and constant polynomial, else return \axiom{[1]}.
removeRoughlyRedundantFactorsInContents : (LP, LP) -> LP
++ \axiom{removeRoughlyRedundantFactorsInContents(lp,lf)} returns
++ \axiom{newlp} where \axiom{newlp} is obtained from \axiom{lp}
++ by removing in the content of every polynomial of \axiom{lp}
++ any occurrence of a polynomial \axiom{f} in \axiom{lf}. Moreover,
++ squares over \axiom{R} are first removed in the content
++ of every polynomial of \axiom{lp}.
removeRedundantFactorsInContents : (LP, LP) -> LP
++ \axiom{removeRedundantFactorsInContents(lp,lf)} returns \axiom{newlp}
++ where \axiom{newlp} is obtained from \axiom{lp} by removing
++ in the content of every polynomial of \axiom{lp} any non trivial
++ factor of any polynomial \axiom{f} in \axiom{lf}. Moreover,
++ squares over \axiom{R} are first removed in the content
++ of every polynomial of \axiom{lp}.
removeRedundantFactorsInPols : (LP, LP) -> LP
++ \axiom{removeRedundantFactorsInPols(lp,lf)} returns \axiom{newlp}
++ where \axiom{newlp} is obtained from \axiom{lp} by removing
++ in every polynomial \axiom{p} of \axiom{lp} any non trivial
++ factor of any polynomial \axiom{f} in \axiom{lf}. Moreover,
++ squares over \axiom{R} are first removed in every
++ polynomial \axiom{lp}.
if (R has EuclideanDomain) and (R has CharacteristicZero)
then
irreducibleFactors : LP -> LP
++ \axiom{irreducibleFactors(lp)} returns \axiom{lf} such that if
++ \axiom{lp} = [p1,...,pn] and \axiom{lf} = [f1,...,fm] then
++ \axiom{p1*p2*...*pn=0} means \axiom{f1*f2*...*fm=0}, and the \axiom{fi}
++ are irreducible over \axiom{R} and are pairwise distinct.
lazyIrreducibleFactors : LP -> LP

```

```

++ \axiom{lazyIrreducibleFactors(lp)} returns \axiom{lf} such that if
++ \axiom{lp = [p1,...,pn]} and \axiom{lf = [f1,...,fm]} then
++ \axiom{p1*p2*...*pn=0} means \axiom{f1*f2*...*fm=0}, and the \axiom{fi}
++ are irreducible over \axiom{R} and are pairwise distinct.
++ The algorithm tries to avoid factorization into irreducible
++ factors as far as possible and makes previously use of gcd
++ techniques over \axiom{R}.
removeIrreducibleRedundantFactors : (LP, LP) -> LP
++ \axiom{removeIrreducibleRedundantFactors(lp,lq)} returns the same
++ as \axiom{irreducibleFactors(concat(lp,lq))} assuming
++ that \axiom{irreducibleFactors(lp)} returns \axiom{lp}
++ up to replacing some polynomial \axiom{pj} in \axiom{lp}
++ by some polynomial \axiom{qj} associated to \axiom{pj}.

```

This package computes square-free decomposition of multivariate polynomials over a coefficient ring which is an arbitrary gcd domain. The requirement on the coefficient domain guarantees that the content can be removed so that factors will be primitive as well as square-free. Over an infinite ring of finite characteristic, it may not be possible to guarantee that the factors are square-free.

## PrimitiveArrayFunctions2 (PRIMARR2)

**Exports:**

map reduce scan

— package PRIMARR2 PrimitiveArrayFunctions2 —

```

)abbrev package PRIMARR2 PrimitiveArrayFunctions2
++ Description:
++ This package provides tools for operating on primitive arrays
++ with unary and binary functions involving different underlying types

PrimitiveArrayFunctions2(A, B): Exports == Implementation where
  A, B: Type

VA ==> PrimitiveArray A
VB ==> PrimitiveArray B
O2 ==> FiniteLinearAggregateFunctions2(A, VA, B, VB)
Exports ==> with
  scan : ((A, B) -> B, VA, B) -> VB
  ++ scan(f,a,r) successively applies
  ++ \spad{reduce(f,x,r)} to more and more leading sub-arrays
  ++ x of primitive array \spad{a}.
  ++ More precisely, if \spad{a} is \spad{[a1,a2,...]}, then
  ++ \spad{scan(f,a,r)} returns
  ++ \spad{[reduce(f,[a1],r),reduce(f,[a1,a2],r),...]}.
  ++
  ++X T1:=PrimitiveArrayFunctions2(Integer,Integer)
  ++X adder(a:Integer,b:Integer):Integer == a+b
  ++X scan(adder,[i for i in 1..10],0)$T1

  reduce : ((A, B) -> B, VA, B) -> B
  ++ reduce(f,a,r) applies function f to each
  ++ successive element of the
  ++ primitive array \spad{a} and an accumulant initialized to r.
  ++ For example, \spad{reduce(_+$Integer,[1,2,3],0)}
  ++ does \spad{3+(2+(1+0))}. Note that third argument r
  ++ may be regarded as the identity element for the function f.
  ++
  ++X T1:=PrimitiveArrayFunctions2(Integer,Integer)
  ++X adder(a:Integer,b:Integer):Integer == a+b
  ++X reduce(adder,[i for i in 1..10],0)$T1

  map : (A -> B, VA) -> VB
  ++ map(f,a) applies function f to each member of primitive array
  ++ \spad{a} resulting in a new primitive array over a
  ++ possibly different underlying domain.
  ++
  ++X T1:=PrimitiveArrayFunctions2(Integer,Integer)
  ++X map(x+->x+2,[i for i in 1..10])$T1

Implementation ==> add

— package ODEPRIM PrimitiveRatDE —

```

)abbrev package ODEPRIM PrimitiveRatDE
++ Author: Manuel Bronstein
++ Date Created: 1 March 1991
++ Date Last Updated: 1 February 1994
++ Description:
++ \spad{PrimitiveRatDE} provides functions for in-field solutions of linear
++ ordinary differential equations, in the transcendental case.
++ The derivation to use is given by the parameter \spad{L}.

PrimitiveRatDE(F, UP, L, LQ): Exports == Implementation where
  F : Join(Field, CharacteristicZero, RetractableTo Fraction Integer)
  UP : UnivariatePolynomialCategory F
  L : LinearOrdinaryDifferentialOperatorCategory UP
  LQ : LinearOrdinaryDifferentialOperatorCategory Fraction UP

N ==> NonNegativeInteger
Z ==> Integer
RF ==> Fraction UP
UP2 ==> SparseUnivariatePolynomial UP
REC ==> Record(center:UP, equation:UP)

Exports ==> with
  denomLODE: (L, RF) -> Union(UP, "failed")
  
```

```

++ denomLODE(op, g) returns a polynomial d such that
++ any rational solution of \spad{op y = g}
++ is of the form \spad{p/d} for some polynomial p, and
++ "failed", if the equation has no rational solution.
denomLODE: (L, List RF) -> UP
++ denomLODE(op, [g1,...,gm]) returns a polynomial
++ d such that any rational solution of \spad{op y = c1 g1 + ... + cm gm}
++ is of the form \spad{p/d} for some polynomial p.
indicialEquations: L -> List REC
++ indicialEquations op returns \spad{[[d1,e1],...,[dq,eq]]} where
++ the \spad{d_i}'s are the affine singularities of \spad{op},
++ and the \spad{e_i}'s are the indicial equations at each \spad{d_i}.
indicialEquations: (L, UP) -> List REC
++ indicialEquations(op, p) returns \spad{[[d1,e1],...,[dq,eq]]} where
++ the \spad{d_i}'s are the affine singularities of \spad{op}
++ above the roots of \spad{p},
++ and the \spad{e_i}'s are the indicial equations at each \spad{d_i}.
indicialEquation: (L, F) -> UP
++ indicialEquation(op, a) returns the indicial equation of \spad{op}
++ at \spad{a}.
indicialEquations: LQ -> List REC
++ indicialEquations op returns \spad{[[d1,e1],...,[dq,eq]]} where
++ the \spad{d_i}'s are the affine singularities of \spad{op},
++ and the \spad{e_i}'s are the indicial equations at each \spad{d_i}.
indicialEquations: (LQ, UP) -> List REC
++ indicialEquations(op, p) returns \spad{[[d1,e1],...,[dq,eq]]} where
++ the \spad{d_i}'s are the affine singularities of \spad{op}

denomRicDE: L -> UP
++ denomRicDE(op) returns a polynomial \spad{d} such that any rational
++ solution of the associated Riccati equation of \spad{op y = 0} is
++ of the form \spad{p/d + q'/q + r} for some polynomials p and q
++ and a reduced r. Also, \spad{deg(p) < deg(d)} and {gcd(d,q) = 1}.
leadingCoefficientRicDE: L -> List REC
++ leadingCoefficientRicDE(op) returns
++ \spad{[[m1, p1], [m2, p2], ... , [mk, pk]]} such that the polynomial
++ part of any rational solution of the associated Riccati equation of
++ \spad{op y = 0} must have degree mj for some j, and its leading
++ coefficient is then a zero of pj. In addition, \spad{m1>m2> ... >mk}.
constantCoefficientRicDE: (L, UP -> List F) -> List CNT
++ constantCoefficientRicDE(op, ric) returns
++ \spad{[[a1, L1], [a2, L2], ... , [ak, Lk]]} such that any rational
++ solution with no polynomial part of the associated Riccati equation of
++ \spad{op y = 0} must be one of the ai's in which case the equation for
++ \spad{z = y e^{-int ai}} is \spad{Li z = 0}.
++ \spad{ric} is a Riccati equation solver over \spad{F}, whose input
++ is the associated linear equation.
polyRicDE: (L, UP -> List F) -> List POL
++ polyRicDE(op, zeros) returns
++ \spad{[[p1, L1], [p2, L2], ... , [pk, Lk]]} such that the polynomial
++ part of any rational solution of the associated Riccati equation of
++ \spad{op y=0} must be one of the pi's (up to the constant coefficient),
++ in which case the equation for \spad{z=y e^{-int p}} is \spad{Li z =0}.
++ \spad{zeros} is a zero finder in \spad{UP}.
singRicDE: (L, (UP, UP2) -> List UP, UP -> Factored UP) -> List FRC
++ singRicDE(op, zeros, ezfactor) returns
++ \spad{[[f1, L1], [f2, L2], ... , [fk, Lk]]} such that the singular
++ part of any rational solution of the associated Riccati equation of
++ \spad{op y=0} must be one of the fi's (up to the constant coefficient),
++ in which case the equation for \spad{z=y e^{-int p}} is \spad{Li z =0}.
++ \spad{zeros(C(x),H(x,y))} returns all the \spad{P_i(x)}'s such that
++ \spad{H(x,P_i(x)) = 0 modulo C(x)}.
++ Argument \spad{ezfactor} is a factorisation in \spad{UP},
```

```

    ++ not necessarily into irreducibles.
changeVar: (L, UP) -> L
    ++ changeVar(+/[ai D^i], a) returns the operator \spad{+/[ai (D+a)^i]}.
changeVar: (L, RF) -> L
    ++ changeVar(+/[ai D^i], a) returns the operator \spad{+/[ai (D+a)^i]}.

PseudoRemainderSequence examples
=====

```

The package constructor PseudoRemainderSequence provides efficient algorithms by Lionel Ducos (University of Poitiers, France) for computing sub-resultants. This leads to a speed up in many places in Axiom where sub-resultants are computed (polynomial system solving, algebraic factorization, integration).

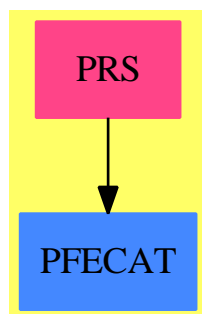

This package contains some functions from improvements of the subresultants algorithm.

## PureAlgebraicIntegration (INTPAF)

**Exports:**

palgLODE palgRDE palgextint palgint palglimit

— package INTPAF PureAlgebraicIntegration —

```

)abbrev package INTPAF PureAlgebraicIntegration
++ Author: Manuel Bronstein
++ Date Created: 27 May 1988
++ Date Last Updated: 24 June 1994
++ Description:
++ Integration of pure algebraic functions;
++ This package provides functions for integration, limited integration,
++ extended integration and the risch differential equation for
++ pure algebraic integrands;

PureAlgebraicIntegration(R, F, L): Exports == Implementation where
  R: Join(GcdDomain,RetractableTo Integer,OrderedSet, CharacteristicZero,
         LinearlyExplicitRingOver Integer)
  F: Join(FunctionSpace R, AlgebraicallyClosedField,
         TranscendentalFunctionCategory)
  L: SetCategory

SY ==> Symbol
N ==> NonNegativeInteger
K ==> Kernel F
P ==> SparseMultivariatePolynomial(R, K)
UP ==> SparseUnivariatePolynomial F
RF ==> Fraction UP
UPUP==> SparseUnivariatePolynomial RF
IR ==> IntegrationResult F
  
```

```

IR2 ==> IntegrationResultFunctions2(curve, F)
ALG ==> AlgebraicIntegrate(R, F, UP, UPUP, curve)
LDALG ==> LinearOrdinaryDifferentialOperator1 curve
RDALG ==> PureAlgebraicLODE(F, UP, UPUP, curve)
LOG ==> Record(coeff:F, logand:F)
REC ==> Record(particular:U1, basis:List F)
CND ==> Record(left:UP, right:UP)
CHV ==> Record(int:UPUP, left:UP, right:UP, den:RF, deg:N)
U1 ==> Union(F, "failed")
U2 ==> Union(Record(ratpart:F, coeff:F), "failed")
U3 ==> Union(Record(mainpart:F, limitedlogs:List LOG), "failed")
FAIL==> error "failed - cannot handle that integrand"

Exports ==> with
  palgint    : (F, K, K)    -> IR
    ++ palgint(f, x, y) returns the integral of \spad{f(x,y)dx}
    ++ where y is an algebraic function of x.
  palgextint: (F, K, K, F) -> U2
    ++ palgextint(f, x, y, g) returns functions \spad{[h, c]} such that
    ++ \spad{dh/dx = f(x,y) - c g}, where y is an algebraic function of x;
    ++ returns "failed" if no such functions exist.
  palglimit: (F, K, K, List F) -> U3
    ++ palglimit(f, x, y, [u1,...,un]) returns functions
    ++ \spad{[h, [[ci, ui]]]} such that the ui's are among \spad{[u1,...,un]}
    ++ and \spad{d(h + sum(ci log(ui)))/dx = f(x,y)} if such functions exist,
    ++ "failed" otherwise;
    ++ y is an algebraic function of x.
  palgrde    : (F, F, F, K, K, (F, F, SY) -> U1) -> U1
    ++ palgrde(nfp, f, g, x, y, foo) returns a function \spad{z(x,y)}
    ++ such that \spad{dz/dx + n * df/dx z(x,y) = g(x,y)} if such a z exists,
    ++ "failed" otherwise;
    ++ y is an algebraic function of x;
    ++ \spad{foo(a, b, x)} is a function that solves
    ++ \spad{du/dx + n * da/dx u(x) = u(x)}
    ++ for an unknown \spad{u(x)} not involving y.
    ++ \spad{nfp} is \spad{n * df/dx}.
  if L has LinearOrdinaryDifferentialOperatorCategory F then
    palgLODE: (L, F, K, K, SY) -> REC
      ++ palgLODE(op, g, kx, y, x) returns the solution of \spad{op f = g}.
      ++ y is an algebraic function of x.

=====
QuasiAlgebraicSet2 examples
=====
```

QuasiAlgebraicSet2 adds a function `radicalSimplify` which uses `IdealDecompositionPackage` to simplify the representation of a quasi-algebraic set.

A quasi-algebraic set is the intersection of a Zariski closed set, defined as the common zeros of a given list of polynomials (the defining polynomials for equations), and a principal Zariski open set, defined as the complement of the common zeros of a polynomial  $f$  (the defining polynomial for the inequation).

Quasi-algebraic sets are implemented in the domain `QuasiAlgebraicSet`, where two simplification routines are provided: `idealSimplify` and `simplify`.

The function `radicalSimplify` is added for comparison study only.

Because the domain `IdealDecompositionPackage` provides facilities for computing with radical ideals, it is necessary to restrict the ground ring to the domain `Fraction Integer`, and the polynomial ring to be of type `DistributedMultivariatePolynomial`.

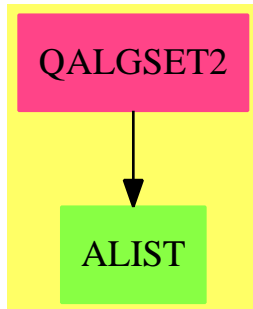

The routine `radicalSimplify` uses these to compute groebner basis of radical ideals and is inefficient and restricted when compared to the two in `QuasiAlgebraicSet`.

=====

QuaternionCategoryFunctions2 examples

=====

QuaternionCategoryFunctions2 implements functions between two quaternion domains. The function map is used by the system interpreter to coerce between quaternion types.

The package QuaternionCategoryFunctions2 provides a function map to convert an expression in Quaternion(R) to an expression in Quaternion(S) using the function f.

```
q := quatern(2/11,-8,3/4,1)
```

```

           2       3
-- - 8i + - j + k
        11       4

```

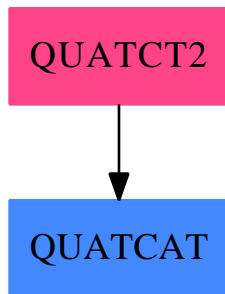

Type: Quaternion Fraction Integer

```
f(a:Fraction Integer):Complex Fraction Integer == a::Complex Fraction Integer
  Function declaration f : Fraction Integer -> Complex Fraction
  Integer has been added to workspace.
  Type: Void
```

```
map(f,q)
  Compiling function f with type Fraction Integer -> Complex Fraction
  Integer
      2      3
  -- - 8i + - j + k
  11      4
  Type: Quaternion Complex Fraction Integer
```

```

Factorization of extended polynomials with rational coefficients. This package implements factorization of extended polynomials whose coefficients are rational numbers. It does this by taking the lcm of the coefficients of the polynomial and creating a polynomial with integer coefficients. The algorithm in GaloisGroupFactorizer is then used to factor the integer polynomial. The result is normalized with respect to the original lcm of the denominators.

-- ... so we replace them by the following 4:
limit: (RF,EQ OrderedCompletion P) -> U
  ++ limit(f(x),x = a) computes the real two-sided limit
  ++ of f as its argument x approaches  $\text{\spad\{a\}}$ .
limit: (RF,EQ RF) -> U
  ++ limit(f(x),x = a) computes the real two-sided limit
  ++ of f as its argument x approaches  $\text{\spad\{a\}}$ .
complexLimit: (RF,EQ OnePointCompletion P) -> OPF
  ++  $\text{\spad\{complexLimit(f(x),x = a)\}}$  computes the complex limit
  ++ of  $\text{\spad\{f\}}$  as its argument x approaches  $\text{\spad\{a\}}$ .
complexLimit: (RF,EQ RF) -> OPF
  ++ complexLimit(f(x),x = a) computes the complex limit
  ++ of f as its argument x approaches  $\text{\spad\{a\}}$ .
limit: (RF,EQ RF,String) -> Result
  ++ limit(f(x),x,a,"left") computes the real limit
  ++ of f as its argument x approaches  $\text{\spad\{a\}}$  from the left;
  ++ limit(f(x),x,a,"right") computes the corresponding limit as x
  ++ approaches  $\text{\spad\{a\}}$  from the right.

**— RationalFunctionSum.help —**

=====  
**RationalFunctionSum examples**  
 =====

Computes sums of rational functions.  
 There are 4 different forms of the sum operator in this domain.  
 They are variations of the types of the input

```
sum(i::Polynomial(Integer),variable(i=1..n))

      2
     6i - 6i + 1
-----
      12
```

```
sum(i::Fraction(Polynomial(Integer)),i::Symbol)
```

$$\frac{6i^2 - 6i + 1}{12}$$

```
sum(i,i=1..n)
```

$$\frac{n^2 + n}{2}$$

```
sum(i::Fraction(Polynomial(Integer)),i=1..n)
```

$$\frac{n^2 + n}{2}$$

We can compute the sum form on part at a time to see what happens.  
First, we make a `SegmentBinding(Polynomial(Integer))`:

```
s:=i=1..n
```

```
i= 1..n
```

We pick out the upper and lower bounds of the segment:

```
hiseg:=high(segment(s))
```

```
n
```

```
loseg:=low(segment(s))
```

```
1
```

We pick out the variable from the segment:

```
v:=variable s
```

i

We create a polynomial we wish to sum:

```
p:=i::Polynomial(Integer)
```

i

And we create the sum for that polynomial:

```
f:=sum(p,v)
```

$$\frac{6i^2 - 6i + 1}{12}$$

The new evaluate it at the upper endpoint:

```
t1:=eval(f,v,(1+hiseq))
```

$$\frac{6n^2 + 6n + 1}{12}$$

And the lower endpoint:

```
t2:=eval(f,v,loseq)
```

$$\frac{1}{12}$$

And we take the difference of the endpoints:

```
t1-t2
```

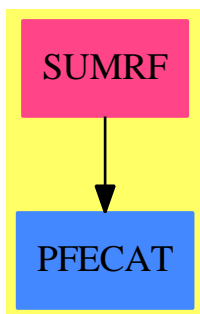

$$\frac{n^2 + n}{2}$$

## package RINTERP RationalInterpolation

### Introduction

This file contains a crude naïve implementation of rational interpolation, where the coefficients of the rational function are in any given field.

### Questions and Outlook

- Maybe this file should be joined with `pinterp.spad`, where polynomial Lagrange interpolation is implemented. I have a second version that parallels the structure of `pinterp.spad` closely.
- There are probably better ways to implement rational interpolation. Maybe <http://www.cs.ucsb.edu/omer/pers> contains something useful, but I don't know.
- Comments welcome!

```

---

First we check whether we have the right number of points and values. Clearly the number of points and the number of values must be identical. Note that we want to determine the numerator and denominator polynomials only up to a factor. Thus, we want to determine  $m + k + 1$  coefficients, where  $m$  is the degree of the polynomial in the numerator and  $k$  is the degree of the polynomial in the denominator.

In fact, we could also leave – for example –  $k$  unspecified and determine it as  $k = \#xlist - m - 1$ : I don't know whether this would be better.

— **package RINTERP RationalInterpolation** —

```

#xlist ^= #ylist =>
  error "Different number of points and values."
#xlist ^= m+k+1 =>
  error "wrong number of points"

```

---

The next step is to set up the matrix. Suppose that our numerator polynomial is  $p(x) = a_0 + a_1x + \dots + a_mx^m$  and that our denominator polynomial is  $q(x) = b_0 + b_1x + \dots + b_kx^k$ . Then we have the following equations, writing  $n$  for  $m + k + 1$ :

$$\begin{aligned}
 p(x_1) - y_1q(x_1) &= a_0 + a_1x_1 + \dots + a_mx_1^m - y_1(b_0 + b_1x_1 + \dots + b_kx_1^k) = 0 \\
 p(x_2) - y_2q(x_2) &= a_0 + a_1x_2 + \dots + a_mx_2^m - y_2(b_0 + b_1x_2 + \dots + b_kx_2^k) = 0 \\
 &\vdots \\
 p(x_n) - y_nq(x_n) &= a_0 + a_1x_n + \dots + a_mx_n^m - y_n(b_0 + b_1x_n + \dots + b_kx_n^k) = 0
 \end{aligned}$$

This can be written as

$$\begin{bmatrix} 1 & x_1 & \dots & x_1^m & -y_1 & -y_1x_1 & \dots & -y_1x_1^k \\ 1 & x_2 & \dots & x_2^m & -y_2 & -y_2x_2 & \dots & -y_2x_2^k \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & x_n & \dots & x_n^m & -y_n & -y_nx_n & \dots & -y_nx_n^k \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ \vdots \\ a_m \\ b_0 \\ b_1 \\ \vdots \\ b_k \end{bmatrix} = \mathbf{0}$$

We generate this matrix columnwise:

```
— package RINTERP RationalInterpolation —
tempvec: List F := [1 for i in 1..(m+k+1)]
collist: List List F := cons(tempvec,
                             [(tempvec := [tempvec.i * xlist.i _
   for i in 1..(m+k+1)]) _
                              for j in 1..max(m,k)])
collist := append([collist.j for j in 1..(m+1)], _
                  [[- collist.j.i * ylist.i for i in 1..(m+k+1)] _
                   for j in 1..(k+1)])
```

Now we can solve the system:

```
— package RINTERP RationalInterpolation —
res: List Vector F := nullSpace((transpose matrix collist) _
                               ::Matrix F)
```

Note that it may happen that the system has several solutions. In this case, some of the data points may not be interpolated correctly. However, the solution is often still useful, thus we do not signal an error.

```
— package RINTERP RationalInterpolation —
if #res~=1 then output("Warning: unattainable points!" _
                      ::OutputForm)$OutputPackage
```

In this situation, all the solutions will be equivalent, thus we can always simply take the first one:

— package RINTERP RationalInterpolation —

```
reslist: List List Polynomial F := _
      [[(res.1).(i+1)*(xx::Polynomial F)**i for i in 0..m], _
      [(res.1).(i+m+2)*(xx::Polynomial F)**i for i in 0..k]]
```

Finally, we generate the rational function:

— package RINTERP RationalInterpolation —

```
reduce((+_),reslist.1)/reduce((+_),reslist.2)
```

— RINTERP.dotabb —

```
"RINTERP" [color="#FF4488",href="bookvol10.4.pdf#nameddest=RINTERP"]
"PFECAT" [color="#4488FF",href="bookvol10.2.pdf#nameddest=PFECAT"]
"RINTERP" -> "PFECAT"
```

## RationalUnivariateRepresentationPackage (RURPK)

**Exports:**

rur

— package RURPK RationalUnivariateRepresentationPackage —

```

)abbrev package RURPK RationalUnivariateRepresentationPackage
++ Author: Marc Moreno Maza
++ Date Created: 01/1999
++ Date Last Updated: 23/01/1999
++ Description:
++ A package for computing the rational univariate representation
++ of a zero-dimensional algebraic variety given by a regular
++ triangular set. This package is essentially an interface for the
++ \spadtype{InternalRationalUnivariateRepresentationPackage} constructor.
++ It is used in the \spadtype{ZeroDimensionalSolvePackage}
++ for solving polynomial systems with finitely many solutions.

RationalUnivariateRepresentationPackage(R,ls): Exports == Implementation where
  R : Join(EuclideanDomain,CharacteristicZero)
  ls: List Symbol
  N ==> NonNegativeInteger
  Z ==> Integer
  P ==> Polynomial R
  LP ==> List P
  U ==> SparseUnivariatePolynomial(R)
  RUR ==> Record(complexRoots: U, coordinates: LP)

Exports == with

  rur: (LP,Boolean) -> List RUR
  ++ \spad{rur(lp,univ?)} returns a rational univariate representation
  ++ of \spad{lp}. This assumes that \spad{lp} defines a regular
  ++ triangular \spad{ts} whose associated variety is zero-dimensional
  ++ over \spad{R}. \spad{rur(lp,univ?)} returns a list of items
  ++ \spad{[u,lc]} where \spad{u} is an irreducible univariate polynomial

```

```

++ and each \spad{c} in \spad{lc} involves two variables: one from \spad{ls},
++ called the coordinate of \spad{c}, and an extra variable which
++ represents any root of \spad{u}. Every root of \spad{u} leads to
++ a tuple of values for the coordinates of \spad{lc}. Moreover,
++ a point \spad{x} belongs to the variety associated with \spad{lp} iff
++ there exists an item \spad{[u,lc]} in \spad{rur(lp,univ?)} and
++ a root \spad{r} of \spad{u} such that \spad{x} is given by the
++ tuple of values for the coordinates of \spad{lc} evaluated at \spad{r}.
++ If \spad{univ?} is \spad{true} then each polynomial \spad{c}
++ will have a constant leading coefficient w.r.t. its coordinate.
++ See the example which illustrates the \spadtype{ZeroDimensionalSolvePackage}
++ package constructor.
rur: (LP) -> List RUR
++ \spad{rur(lp)} returns the same as \spad{rur(lp,true)}
rur: (LP,Boolean,Boolean) -> List RUR
++ \spad{rur(lp,univ?,check?)} returns the same as \spad{rur(lp,true)}.
++ Moreover, if \spad{check?} is \spad{true} then the result is checked.

## package POLUTIL RealPolynomialUtilitiesPackage

This file describes the Real Closure 1.0 package which consists of different packages, categories and domains.

The package RealPolynomialUtilitiesPackage which receives a field and a univariate polynomial domain with coefficients in the field. It computes some simple functions such as Strum and Sylvester sequences.

The category RealRootCharacterizationCategory provides abstract functionalities to work with "real roots" of univariate polynomials. These resemble variables with some functionalities needed to compute important operations.

RealClosedField is a category with provides common operations available over real closed fiels. These include finding all the roots of univariate polynomial, taking square roots, ...

### CAVEATS

Since real algebraic expressions are stored as depending on "real roots" which are managed like variables, there is an ordering on these. This ordering is dynamical in the sense that any new algebraic takes precedence over older ones. In particular every cretaion function raises a new "real root". This has the effect that when you type something like  $\sqrt{2} + \sqrt{2}$  you have two new variables which happen to be equal. To avoid this name the expression such as in  $s2 := \sqrt{2} ; s2 + s2$

Also note that computing times depend strongly on the ordering you implicitly provide. Please provide algebraics in the order which most natural to you.

### LIMITATIONS

The file reclos.input show some basic use of the package. This packages uses algorithms which are published in [1] and [2] which are based on field arithmetics, in particular for polynomial gcd related algorithms. This can be quite slow for high degree polynomials and subresultants methods usually work best. Beta versions of the package try to use these techniques in a better way and work significantly faster. These are mostly based on unpublished algorithms and cannot be distributed. Please contact the author if you have a particular problem to solve or want to use these versions.

Be aware that approximations behave as post-processing and that all computations are done excatly. They can thus be quite time consuming when depending on several "real roots".

--RecurrenceOperator(F): Exports == Implementation where
-- F: Join(ExpressionSpace, AbelianMonoid, RetractableTo Integer,
--         RetractableTo Symbol, PartialDifferentialRing Symbol)

```

Exports == with

```

evalRec: (BasicOperator, Symbol, F, F, F, List F) -> F
++ \spad{evalRec(u, dummy, n, n0, eq, values)} creates an expression that
++ stands for u(n0), where u(n) is given by the equation eq. However, for
++ technical reasons the variable n has to be replaced by a dummy
++ variable dummy in eq. The argument values specifies the initial values
++ of the recurrence u(0), u(1),...
++ For the moment we don't allow recursions that contain u inside of
++ another operator.

```

```

evalADE: (BasicOperator, Symbol, F, F, F, List F) -> F
++ \spad{evalADE(f, dummy, x, n, eq, values)} creates an expression that

```

```

++ stands for the coefficient of x^n in the Taylor expansion of f(x),
++ where f(x) is given by the functional equation eq. However, for
++ technical reasons the variable x has to be replaced by a dummy
++ variable dummy in eq. The argument values specifies the first few
++ Taylor coefficients.

getEq: F -> F
++ \spad{getEq f} returns the defining equation, if f represents the
++ coefficient of an ADE or a recurrence.

getOp: F -> BasicOperator
++ \spad{getOp f}, if f represents the coefficient of a recurrence or
++ ADE, returns the operator representing the solution

            ord: Union(Integer, "failed"),
            ker: Kernel F)

  Implementation == add
\getchunk{implementation: RecurrenceOperator}

```

---

## Defining new operators

We define two new operators, one for recurrences, the other for functional equations. The operators for recurrences represents the  $n^{\text{th}}$  term of the corresponding sequence, the other the coefficient of  $x^n$  in the Taylor series expansion.

— implementation: RecurrenceOperator —

```

oprecur := operator("rootOfRec"::Symbol)$BasicOperator

opADE := operator("rootOfADE"::Symbol)$BasicOperator

setProperty(oprecur, "%dummyVar", 2 pretend None)
setProperty(opADE, "%dummyVar", 2 pretend None)

```

---

Setting these properties implies that the second and third arguments of `oprecur` are dummy variables and affects `tower$ES`: the second argument will not appear in `tower$ES`, if it does not appear in any argument but the first and second. The third argument will not appear in `tower$ES`, if it does not appear in any other argument. (`%defsum` is a good example)

The arguments of the two operators are as follows:

1. `eq`, i.e. the vanishing expression

— **implementation: RecurrenceOperator** —

```
eqAsF: List F -> F
eqAsF l == l.1
```

---

2. `dummy`, a dummy variable to make substitutions possible

— **implementation: RecurrenceOperator** —

```
dummy: List F -> Symbol
dummy l == retract(l.2)@Symbol

dummyAsF: List F -> F
dummyAsF l == l.2
```

---

3. the variable for display

— **implementation: RecurrenceOperator** —

```
displayVariable: List F -> F
displayVariable l == l.3
```

---

4. `operatorName(argument)`

— **implementation: RecurrenceOperator** —

```
operatorName: List F -> BasicOperator
operatorName l == operator(kernels(l.4).1)

operatorNameAsF: List F -> F
operatorNameAsF l == l.4

operatorArgument: List F -> F
operatorArgument l == argument(kernels(l.4).1).1
```

---

Concerning `rootOfADE`, note that although we have `arg` as argument of the operator, it is intended to indicate the coefficient, not the argument of the power series.

5. values in reversed order.

- `rootOfRec`: maybe values should be preceded by the index of the first given value. Currently, the last value is interpreted as  $f(0)$ .
- `rootOfADE`: values are the first few coefficients of the power series expansion in order.

— implementation: `RecurrenceOperator` —

```
initialValues: List F -> List F
initialValues l == rest(l, 4)
```

---

## Recurrences

### Extracting some information from the recurrence

We need to find out whether we can determine the next term of the sequence, and how many initial values are necessary.

— implementation: `RecurrenceOperator` —

```
if R has Ring then
  getShiftRec(op: BasicOperator, f: Kernel F, n: Symbol)
    : Union(Integer, "failed") ==
  a := argument f
  if every?(z +-> freeOf?(z, n::F), a) then return 0

  if #a ~= 1 then error "RECOP: operator should have only one argument"

  p := univariate(a.1, retract(n::F)@Kernel(F))
  if denominator p ~= 1 then return "failed"

  num := numer p

  if degree num = 1 and coefficient(num, 1) = 1
    and every?(z +-> freeOf?(z, n::F), coefficients num)
  then return retractIfCan(coefficient(num, 0))
  else return "failed"
```

```

-- if the recurrence is of the form
-- $p(n, f(n+m-o), f(n+m-o+1), \dots, f(n+m)) = 0$
-- in which case shiftInfoRec returns [m, o, f(n+m)].

    shiftInfoRec(op: BasicOperator, argsym: Symbol, eq: F):
        Record(max: Union(Integer, "failed"),
              ord: Union(Integer, "failed"),
              ker: Kernel F) ==

-- ord and ker are valid only if all shifts are Integers
-- ker is the kernel of the maximal shift.
    maxShift: Integer
    minShift: Integer
    nextKernel: Kernel F

-- We consider only those kernels that have op as operator. If there is none,
-- we raise an error. For the moment we don't allow recursions that contain op
-- inside of another operator.

    error? := true

for f in kernels eq repeat
  if is?(f, op) then
    shift := getShiftRec(op, f, argsym)
    if error? then
      error? := false
      nextKernel := f
      if shift case Integer then
        maxShift := shift
        minShift := shift
      else return ["failed", "failed", nextKernel]
    else
      if shift case Integer then
        if maxShift < shift then
          maxShift := shift
          nextKernel := f
        if minShift > shift then
          minShift := shift
        else return ["failed", "failed", nextKernel]

if error? then error "evalRec: equation does not contain operator"

[maxShift, maxShift - minShift, nextKernel]

```

---

## Evaluating a recurrence

— implementation: RecurrenceOperator —

```

evalRec(op, argsym, argdisp, arg, eq, values) ==
  if ((n := retractIfCan(arg)@Union(Integer, "failed")) case "failed")
    or (n < 0)
  then
    shiftInfo := shiftInfoRec(op, argsym, eq)

    if (shiftInfo.ord case "failed") or ((shiftInfo.ord)::Integer > 0)
    then
      kernel(oprecur,
        append([eq, argsym::F, argdisp, op(arg)], values))
    else
      p := univariate(eq, shiftInfo.ker)
      num := numer p

-- If the degree is 1, we can return the function explicitly.

    if degree num = 1 then
      eval(-coefficient(num, 0)/coefficient(num, 1), argsym::F,
        arg::F-(shiftInfo.max)::Integer::F)
    else
      kernel(oprecur,
        append([eq, argsym::F, argdisp, op(arg)], values))
  else
    len: Integer := #values
    if n < len
    then values.(len-n)
    else
      shiftInfo := shiftInfoRec(op, argsym, eq)

      if shiftInfo.max case Integer then
        p := univariate(eq, shiftInfo.ker)

        num := numer p

        if degree num = 1 then

          next := -coefficient(num, 0)/coefficient(num, 1)
          nextval := eval(next, argsym::F,
            (len-(shiftInfo.max)::Integer)::F)
          newval := eval(nextval, op,
            z+->evalRec(op, argsym, argdisp, z, eq, values))
          evalRec(op, argsym, argdisp, arg, eq, cons(newval, values))
        else
          kernel(oprecur,
            append([eq, argsym::F, argdisp, op(arg)], values))

```

```

else
  kernel(oprecur,
    append([eq, argsym::F, argdisp, op(arg)], values))

numberOfValuesNeeded(numberOfValues: Integer,
  op: BasicOperator,
  argsym: Symbol, eq: F): Integer ==
order := shiftInfoRec(op, argsym, eq).ord
if order case Integer
then min(numberOfValues, retract(order)@Integer)
else numberOfValues

else
evalRec(op, argsym, argdisp, arg, eq, values) ==
kernel(oprecur,
  append([eq, argsym::F, argdisp, op(arg)], values))

numberOfValuesNeeded(numberOfValues: Integer,
  op: BasicOperator, argsym: Symbol, eq: F): Integer ==
numberOfValues

```

---

### Setting the evaluation property of oprecur

irecur is just a wrapper that allows us to write a recurrence relation as an operator.

— implementation: RecurrenceOperator —

```

irecur: List F -> F
irecur l ==
  evalRec(operatorName l,
    dummy l, displayVariable l,
    operatorArgument l, eqAsF l, initialValues l)

evaluate(oprecur, irecur)$BasicOperatorFunctions1(F)

```

---

### Displaying a recurrence relation

— implementation: RecurrenceOperator —

```

ddrec: List F -> OutputForm
ddrec l ==
  op := operatorName l
  values := reverse l
  eq := eqAsF l

  numberOfValues := numberOfValuesNeeded(#values-4, op, dummy l, eq)

  vals: List OutputForm
  := cons(eval(eq, dummyAsF l, displayVariable l)::OutputForm = _
    0::OutputForm,
    [elt(op::OutputForm, [(i-1)::OutputForm]) = _
      (values.i)::OutputForm
      for i in 1..numberOfValues])

  bracket(hconcat([(operatorNameAsF l)::OutputForm,
    ": ",
    commaSeparate vals])))

setProperty(oprecur, "%specialDisp",
  ddrec@(List F -> OutputForm) pretend None)

```

---

## Functional Equations

### Determining the number of initial values for ADE's

We use Joris van der Hoeven's instructions for ADE's. Given  $Q = p(f, f', \dots, f^{(r)})$  we first need to differentiate  $Q$  with respect to  $f^{(i)}$  for  $i \in \{0, 1, \dots, r\}$ , plug in the given truncated power series solution and determine the valuation.

— NOTYET implementation: RecurrenceOperator —

```

getValuation(op, argsym, eq, maxorder, values): Integer ==
  max: Integer := -1;
  ker: Kernel F
  for i in 0..maxorder repeat
    ker := D(op(argsym), argsym, i)::Kernel F
    pol := univariate(eq, ker)
    dif := D pol
    ground numer(dif.D(op(argsym), argsym, i))

```

---

**Extracting some information from the functional equation**

getOrder returns the maximum derivative of op occurring in f.

— implementation: RecurrenceOperator —

```
getOrder(op: BasicOperator, f: Kernel F): NonNegativeInteger ==
  res: NonNegativeInteger := 0
  g := f
  while is?(g, %diff) repeat
    g := kernels(argument(g).1).1
    res := res+1

  if is?(g, op) then res else 0
```

### — RegularSetDecompositionPackage.help —

```

=====
RegularSetDecompositionPackage examples
=====

```

A package providing a new algorithm for solving polynomial systems by

means of regular chains. Two ways of solving are proposed: in the sense of Zariski closure (like in Kalkbrener's algorithm) or in the sense of the regular zeros (like in Wu, Wang or Lazard methods). This algorithm is valid for any type of regular set. It does not care about the way a polynomial is added in an regular set, or how two quasi-components are compared (by an inclusion-test), or how the invertibility test is made in the tower of simple extensions associated with a regular set.

These operations are realized respectively by the domain TS and the packages QCMPACK(R,E,V,P,TS) and RSETGCD(R,E,V,P,TS).

The same way it does not care about the way univariate polynomial gcd (with coefficients in the tower of simple extensions associated with a regular set) are computed. The only requirement is that these gcd need to have invertible initials (normalized or not).

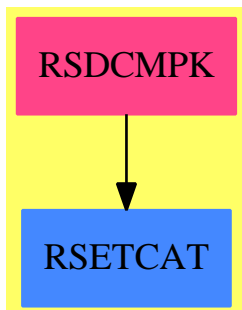

WARNING. There is no need for a user to call directly any operation of this package since they can be accessed by the domain TS. Thus, the operations of this package are not documented.

### — RepeatedSquaring.help —

```

=====
RepeatedSquaring examples
=====

```

This code computes  $x^n$  by repeated squaring. It takes advantage of the law of exponents so that if  $n=a*b$  then

$$x^n = x^a x^b$$

It also takes advantage of the fact that  $n$  has a binary representation so that a one-bit right-shift of a number divides it by 2. Thus we get three cases:

```

n = 1  -> x^1
n odd  -> repeatedsquare(x*x,n/2)*x

```

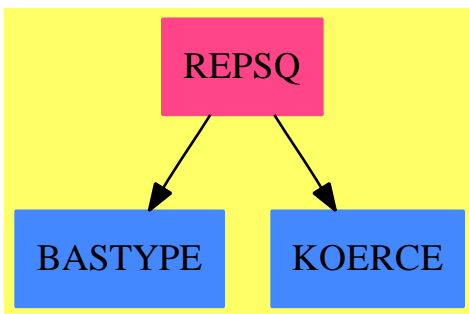

```
n even -> repeatedsquare(x*x,n/2)
```

Since each recursive call divides  $n$  by 2 the algorithm is  $O(\log(n))$ .

```

RepresentationPackage1 provides functions for representation theory for finite groups and algebras.

The package creates permutation representations and uses tensor products and its symmetric and antisymmetric components to create new representations of larger degree from given ones.

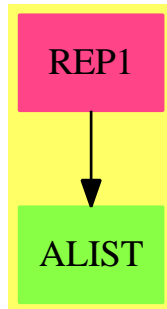

Note that instead of having parameters from Permutation this package allows list notation of permutations as well: e.g. [1,4,3,2] denotes permutes 2 and 4 and fixes 1 and 3.

if R has commutative("*") then
  antisymmetricTensors : (M R,PI) -> M R
  ++ antisymmetricTensors(a,n) applies to the square matrix
  ++ a the irreducible, polynomial representation of the
  ++ general linear group GLm, where m is the number of
  ++ rows of a, which corresponds to the partition
  ++ (1,1,...,1,0,0,...,0) of n.
  ++ Error: if n is greater than m.
  ++ Note that this corresponds to the symmetrization of the
  ++ representation with the sign representation of the symmetric group
  ++ Sn. The carrier spaces of the representation are the antisymmetric
  ++ tensors of the n-fold tensor product.
if R has commutative("*") then
  antisymmetricTensors : (L M R, PI) -> L M R
  ++ antisymmetricTensors(la,n) applies to each
  ++ m-by-m square matrix in
  ++ the list la the irreducible, polynomial representation
  ++ of the general linear group GLm
  ++ which corresponds
  ++ to the partition (1,1,...,1,0,0,...,0) of n.
  ++ Error: if n is greater than m.
  ++ Note that this corresponds to the symmetrization of the
  ++ representation with the sign representation of the symmetric group
  ++ Sn. The carrier spaces of the representation are the antisymmetric
  ++ tensors of the n-fold tensor product.
createGenericMatrix : NNI -> M P R
  ++ createGenericMatrix(m) creates a square matrix of dimension k
  ++ whose entry at the i-th row and j-th column is the
  ++ indeterminate x[i,j] (double subscripted).
symmetricTensors : (M R, PI) -> M R
  ++ symmetricTensors(a,n) applies to the m-by-m
  ++ square matrix a the
  ++ irreducible, polynomial representation of the general linear
  ++ group GLm
  ++ which corresponds to the partition (n,0,...,0) of n.
  ++ Error: if a is not a square matrix.
  ++ Note that this corresponds to the symmetrization of the

```

```

++ representation with the trivial representation of the symmetric
++ group Sn.
++ The carrier spaces of the representation are the symmetric
++ tensors of the n-fold tensor product.
symmetricTensors : (L M R, PI) -> L M R
++ symmetricTensors(la,n) applies to each m-by-m square matrix in the
++ list la the irreducible, polynomial representation
++ of the general linear group GLm
++ which corresponds
++ to the partition (n,0,...,0) of n.
++ Error: if the matrices in la are not square matrices.
++ Note that this corresponds to the symmetrization of the
++ representation with the trivial representation of the symmetric
++ group Sn.
++ The carrier spaces of the representation are the symmetric
++ tensors of the n-fold tensor product.
tensorProduct : (M R, M R) -> M R
++ tensorProduct(a,b) calculates the Kronecker product
++ of the matrices a and b.
++ Note that if each matrix corresponds to a group representation
++ (repr. of generators) of one group, then these matrices
++ correspond to the tensor product of the two representations.
tensorProduct : (L M R, L M R) -> L M R
++ tensorProduct([a1,...,ak],[b1,...,bk]) calculates the list of
++ Kronecker products of the matrices ai and bi
++ for {1 <= i <= k}.
++ Note that if each list of matrices corresponds to a group
++ representation (repr. of generators) of one group, then these
++ matrices correspond to the tensor product of the two representations.
tensorProduct : M R -> M R
++ tensorProduct(a) calculates the Kronecker product
++ of the matrix a with itself.
tensorProduct : L M R -> L M R
++ tensorProduct([a1,...,ak]) calculates the list of
++ Kronecker products of each matrix ai with itself
++ for {1 <= i <= k}.
++ Note that if the list of matrices corresponds to a group
++ representation (repr. of generators) of one group, then these
++ matrices correspond to the tensor product of the representation
++ with itself.
permutationRepresentation : (PERM I, I) -> M I
++ permutationRepresentation(pi,n) returns the matrix
++ (deltai,pi(i)) (Kronecker delta) for a permutation
++ pi of {1,2,...,n}.
permutationRepresentation : L I -> M I
++ permutationRepresentation(pi,n) returns the matrix
++ (deltai,pi(i)) (Kronecker delta) if the permutation
++ pi is in list notation and permutes {1,2,...,n}.
permutationRepresentation : (L PERM I, I) -> L M I
++ permutationRepresentation([pi1,...,pik],n) returns the list

```

```

++ of matrices [(deltai,pi1(i)),...,(deltai,pik(i))]
++ (Kronecker delta) for the permutations pi1,...,pik
++ of {1,2,...,n}.
permutationRepresentation : L L I -> L M I
++ permutationRepresentation([pi1,...,pik],n) returns the list
++ of matrices [(deltai,pi1(i)),...,(deltai,pik(i))]
++ if the permutations pi1,...,pik are in
++ list notation and are permuting {1,2,...,n}.

RepresentationPackage2 provides functions for working with modular representations of finite groups and algebra. The routines in this package are created, using ideas of R. Parker, (the meat-Axe) to get smaller representations from bigger ones, i.e. finding sub- and factormodules, or to show, that such the representations are irreducible.

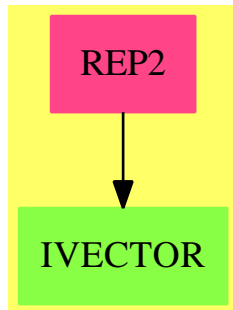

Note that most functions are randomized functions of Las Vegas type i.e. every answer is correct, but with small probability the algorithm fails to get an answer.

public ==> with
```

```

completeEchelonBasis : V V R -> M R
++ completeEchelonBasis(lv) completes the basis lv assumed
++ to be in echelon form of a subspace of R**n (n the length
++ of all the vectors in lv with unit vectors to a basis of
++ R**n. It is assumed that the argument is not an empty
++ vector and that it is not the basis of the 0-subspace.
++ Note that the rows of the result correspond to the vectors
++ of the basis.
createRandomElement : (L M R, M R) -> M R
++ createRandomElement(aG,x) creates a random element of the group
++ algebra generated by aG.
-- randomWord : (L L I, L M) -> M R

```

```

---+ You can create your own 'random' matrix with "randomWord(lli, lm)".
---+ Each li in lli determines a product of matrices, the entries in li
---+ determine which matrix from lm is chosen. Finally we sum over all
---+ products. The result "sm" can be used to call split with (e.g.)
---+ second parameter "first nullSpace sm"
if R has EuclideanDomain then -- using rowEchelon
cyclicSubmodule : (L M R, V R) -> V V R
++ cyclicSubmodule(lm,v) generates a basis as follows.
++ It is assumed that the size n of the vector equals the number
++ of rows and columns of the matrices. Then the matrices generate
++ a subalgebra, say \spad{A}, of the algebra of all square matrices of
++ dimension n. V R is an \spad{A}-module in the natural way.
++ cyclicSubmodule(lm,v) generates the R-Basis of Av as
++ described in section 6 of R. A. Parker's "The Meat-Axe".
++ Note that in contrast to the description in "The Meat-Axe" and to
++ standardBasisOfCyclicSubmodule the result is in echelon form.
standardBasisOfCyclicSubmodule : (L M R, V R) -> M R
++ standardBasisOfCyclicSubmodule(lm,v) returns a matrix as follows.
++ It is assumed that the size n of the vector equals the number
++ of rows and columns of the matrices. Then the matrices generate
++ a subalgebra, say \spad{A},
++ of the algebra of all square matrices of
++ dimension n. V R is an \spad{A}-module in the natural way.
++ standardBasisOfCyclicSubmodule(lm,v) calculates a matrix whose
++ non-zero column vectors are the R-Basis of Av achieved
++ in the way as described in section 6
++ of R. A. Parker's "The Meat-Axe".
++ Note that in contrast to cyclicSubmodule, the result is not
++ in echelon form.
if R has Field then -- only because of inverse in SM
areEquivalent? : (L M R, L M R, B, I) -> M R
++ areEquivalent?(aG0,aG1,randomelements,numberOfTries) tests
++ whether the two lists of matrices, all assumed of same
++ square shape, can be simultaneously conjugated by a non-singular
++ matrix. If these matrices represent the same group generators,
++ the representations are equivalent.
++ The algorithm tries
++ numberOfTries times to create elements in the
++ generated algebras in the same fashion. If their ranks differ,
++ they are not equivalent. If an
++ isomorphism is assumed, then
++ the kernel of an element of the first algebra
++ is mapped to the kernel of the corresponding element in the
++ second algebra. Now consider the one-dimensional ones.
++ If they generate the whole space (e.g. irreducibility !)
++ we use standardBasisOfCyclicSubmodule to create the
++ only possible transition matrix. The method checks whether the
++ matrix conjugates all corresponding matrices from aGi.
++ The way to choose the singular matrices is as in meatAxe.
++ If the two representations are equivalent, this routine

```

```

    ++ returns the transformation matrix TM with
    ++ aG0.i * TM = TM * aG1.i for all i. If the representations
    ++ are not equivalent, a small 0-matrix is returned.
    ++ Note that the case
    ++ with different sets of group generators cannot be handled.
areEquivalent? : (L M R, L M R) -> M R
    ++ areEquivalent?(aG0,aG1) calls areEquivalent?(aG0,aG1,true,25).
    ++ Note that the choice of 25 was rather arbitrary.
areEquivalent? : (L M R, L M R, I) -> M R
    ++ areEquivalent?(aG0,aG1,numberOfTries) calls
    ++ areEquivalent?(aG0,aG1,true,25).
    ++ Note that the choice of 25 was rather arbitrary.
isAbsolutelyIrreducible? : (L M R, I) -> B
    ++ isAbsolutelyIrreducible?(aG, numberOfTries) uses
    ++ Norton's irreducibility test to check for absolute
    ++ irreducibility, assuming if a one-dimensional kernel is found.
    ++ As no field extension changes create "new" elements
    ++ in a one-dimensional space, the criterium stays true
    ++ for every extension. The method looks for one-dimensionals only
    ++ by creating random elements (no fingerprints) since
    ++ a run of meatAxe would have proved absolute irreducibility
    ++ anyway.
isAbsolutelyIrreducible? : L M R -> B
    ++ isAbsolutelyIrreducible?(aG) calls
    ++ isAbsolutelyIrreducible?(aG,25).
    ++ Note that the choice of 25 was rather arbitrary.
split : (L M R, V R) -> L L M R
    ++ split(aG, vector) returns a subalgebra \spad{A} of all
    ++ square matrix of dimension n as a list of list of matrices,
    ++ generated by the list of matrices aG, where n denotes both
    ++ the size of vector as well as the dimension of each of the
    ++ square matrices.
    ++ V R is an A-module in the natural way.
    ++ split(aG, vector) then checks whether the cyclic submodule
    ++ generated by vector is a proper submodule of V R.
    ++ If successful, it returns a two-element list, which contains
    ++ first the list of the representations of the submodule,
    ++ then the list of the representations of the factor module.
    ++ If the vector generates the whole module, a one-element list
    ++ of the old representation is given.
    ++ Note that a later version this should call the other split.
split: (L M R, V V R) -> L L M R
    ++ split(aG,submodule) uses a proper submodule of R**n
    ++ to create the representations of the submodule and of
    ++ the factor module.
if (R has Finite) and (R has Field) then
meatAxe : (L M R, B, I, I) -> L L M R
    ++ meatAxe(aG,randomElements,numberOfTries, maxTests) returns
    ++ a 2-list of representations as follows.
    ++ All matrices of argument aG are assumed to be square

```

```

++ and of equal size.
++ Then \spad{aG} generates a subalgebra, say \spad{A}, of the algebra
++ of all square matrices of dimension n. V R is an A-module
++ in the usual way.
++ meatAxe(aG,numberOfTries, maxTests) creates at most
++ numberOfTries random elements of the algebra, tests
++ them for singularity. If singular, it tries at most maxTests
++ elements of its kernel to generate a proper submodule.
++ If successful, a 2-list is returned: first, a list
++ containing first the list of the
++ representations of the submodule, then a list of the
++ representations of the factor module.
++ Otherwise, if we know that all the kernel is already
++ scanned, Norton's irreducibility test can be used either
++ to prove irreducibility or to find the splitting.
++ If randomElements is false, the first 6 tries
++ use Parker's fingerprints.
meatAxe : L M R -> L L M R
++ meatAxe(aG) calls meatAxe(aG,false,25,7) returns
++ a 2-list of representations as follows.
++ All matrices of argument \spad{aG} are assumed to be square
++ and of
++ equal size. Then \spad{aG} generates a subalgebra,
++ say \spad{A}, of the algebra
++ of all square matrices of dimension n. V R is an A-module
++ in the usual way.
++ meatAxe(aG) creates at most 25 random elements
++ of the algebra, tests
++ them for singularity. If singular, it tries at most 7
++ elements of its kernel to generate a proper submodule.
++ If successful a list which contains first the list of the
++ representations of the submodule, then a list of the
++ representations of the factor module is returned.
++ Otherwise, if we know that all the kernel is already
++ scanned, Norton's irreducibility test can be used either
++ to prove irreducibility or to find the splitting.
++ Notes: the first 6 tries use Parker's fingerprints.
++ Also, 7 covers the case of three-dimensional kernels over
++ the field with 2 elements.
meatAxe: (L M R, B) -> L L M R
++ meatAxe(aG, randomElements) calls meatAxe(aG,false,6,7),
++ only using Parker's fingerprints, if randomElemnts is false.
++ If it is true, it calls meatAxe(aG,true,25,7),
++ only using random elements.
++ Note that the choice of 25 was rather arbitrary.
++ Also, 7 covers the case of three-dimensional kernels over the field
++ with 2 elements.
meatAxe : (L M R, PI) -> L L M R
++ meatAxe(aG, numberOfTries) calls
++ meatAxe(aG,true,numberOfTries,7).

```

```

    ++ Notes: 7 covers the case of three-dimensional
    ++ kernels over the field with 2 elements.
scanOneDimSubspaces: (L V R, I) -> V R
    ++ scanOneDimSubspaces(basis,n) gives a canonical representative
    ++ of the n-th one-dimensional subspace of the vector space
    ++ generated by the elements of basis, all from R**n.
    ++ The coefficients of the representative are of shape
    ++ (0,...,0,1,...,*), * in R. If the size of R
    ++ is q, then there are (q**n-1)/(q-1) of them.
    ++ We first reduce n modulo this number, then find the
    ++ largest i such that +/[q**i for i in 0..i-1] <= n.
    ++ Subtracting this sum of powers from n results in an
    ++ i-digit number to basis q. This fills the positions of the
    ++ stars.
    -- would prefer to have (V V R,...) but nullSpace results
    -- in L V R

### ResolveLatticeCompletion (RESLATC)

**Exports:**

coerce

— package RESLATC ResolveLatticeCompletion —

```

)abbrev package RESLATC ResolveLatticeCompletion
++ Author: Stephen M. Watt

```

```

++ Date Created: 1986
++ Date Last Updated: May 30, 1991
++ Description:
++ This package provides coercions for the special types \spadtype{Exit}
++ and \spadtype{Void}.

ResolveLatticeCompletion(S: Type): with
  coerce: S -> Void
    ++ coerce(s) throws all information about s away.
    ++ This coercion allows values of any type to appear
    ++ in contexts where they will not be used.
    ++ For example, it allows the resolution of different types in
    ++ the \spad{then} and \spad{else} branches when an \spad{if}
    ++ is in a context where the resulting value is not used.
  coerce: Exit -> S
    ++ coerce(e) is never really evaluated. This coercion is
    ++ used for formal type correctness when a function will not
    ++ return directly to its caller.

== add
  coerce(s: S): Void == void()
  coerce(e: Exit): S ==
    error "Bug: Should not be able to obtain value of type Exit"

=====
RootsFindingPackage examples
=====

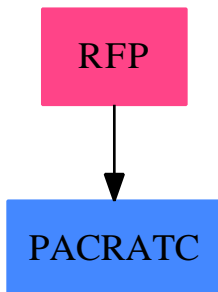

```

This package finds all the roots of a polynomial. If the constant field is not large enough then it returns the list of found zeros and the degree of the extension need to find the other roots missing. If the return degree is 1 then all the roots have been found. If 0 is return for the extension degree then there are an infinite number of zeros, that is you ask for the zeroes of 0. In the case of infinite field a list of all found zeros is kept and for each other call of a function that finds zeroes, a check is made on that list; this is to keep a kind of "canonical" representation of the elements.

SortedCache examples
=====

```

A sorted cache of a cachable set  $S$  is a dynamic structure that keeps the elements of  $S$  sorted and assigns an integer to each element of  $S$  once it is in the cache. This way, equality and ordering on  $S$  are tested directly on the integers associated with the elements of  $S$ , once they have been entered in the cache.

Exports == with
  startTable!: (S,S,S) -> Void
  ++ \axiom{startTableGcd!(s1,s2,s3)}
  ++ is an internal subroutine, exported only for developement.
  stopTable!: () -> Void
  ++ \axiom{stopTableGcd!()}
  ++ is an internal subroutine, exported only for developement.
  supDimElseRittWu?: (TS,TS) -> Boolean
  ++ \axiom{supDimElseRittWu(ts,us)} returns true iff \axiom{ts}
  ++ has less elements than \axiom{us} otherwise if \axiom{ts}
  ++ has higher rank than \axiom{us} w.r.t. Riit and Wu ordering.
  algebraicSort: Split -> Split
  ++ \axiom{algebraicSort(lts)} sorts \axiom{lts} w.r.t
  ++ supDimElseRittWu from QuasiComponentPackage.
  moreAlgebraic?: (TS,TS) -> Boolean
  ++ \axiom{moreAlgebraic?(ts,us)} returns false iff \axiom{ts}
  ++ and \axiom{us} are both empty, or \axiom{ts}
  ++ has less elements than \axiom{us}, or some variable is
  ++ algebraic w.r.t. \axiom{us} and is not w.r.t. \axiom{ts}.
  subTriSet?: (TS,TS) -> Boolean
  ++ \axiom{subTriSet?(ts,us)} returns true iff \axiom{ts} is
  ++ a sub-set of \axiom{us}.
  subPolSet?: (LP, LP) -> Boolean
  ++ \axiom{subPolSet?(lp1,lp2)} returns true iff \axiom{lp1} is
  ++ a sub-set of \axiom{lp2}.
  internalSubPolSet?: (LP, LP) -> Boolean
  ++ \axiom{internalSubPolSet?(lp1,lp2)} returns true iff \axiom{lp1} is
  ++ a sub-set of \axiom{lp2} assuming that these lists are sorted
  ++ increasingly w.r.t.
  ++ infRittWu? from RecursivePolynomialCategory.
  internalInfRittWu?: (LP, LP) -> Boolean
  ++ \axiom{internalInfRittWu?(lp1,lp2)}
  ++ is an internal subroutine, exported only for developement.
  infRittWu?: (LP, LP) -> Boolean
  ++ \axiom{infRittWu?(lp1,lp2)}

```

```

++ is an internal subroutine, exported only for developement.
internalSubQuasiComponent?: (TS,TS) -> Union(Boolean,"failed")
++ \axiom{internalSubQuasiComponent?(ts,us)} returns a boolean
++ \spad{b} value if the fact the regular zero set of \axiom{us}
++ contains that of \axiom{ts} can be decided (and in that case
++ \axiom{b} gives this inclusion) otherwise returns \axiom{"failed"}.
subQuasiComponent?: (TS,TS) -> Boolean
++ \axiom{subQuasiComponent?(ts,us)} returns true iff
++ internalSubQuasiComponent?(ts,us) from QuasiComponentPackage
++ returns true.
subQuasiComponent?: (TS,Split) -> Boolean
++ \axiom{subQuasiComponent?(ts,lus)} returns true iff
++ \axiom{subQuasiComponent?(ts,us)} holds for one
++ \spad{us} in \spad{lus}.
removeSuperfluousQuasiComponents: Split -> Split
++ \axiom{removeSuperfluousQuasiComponents(lts)} removes from
++ \axiom{lts} any \spad{ts} such that
++ \axiom{subQuasiComponent?(ts,us)} holds for
++ another \spad{us} in \axiom{lts}.
subCase?: (LpWT,LpWT) -> Boolean
++ \axiom{subCase?(lpwt1,lpwt2)}
++ is an internal subroutine, exported only for developement.
removeSuperfluousCases: List LpWT -> List LpWT
++ \axiom{removeSuperfluousCases(llpwt)}
++ is an internal subroutine, exported only for developement.
prepareDecompose: (LP, List(TS),B,B) -> List Branch
++ \axiom{prepareDecompose(lp,lts,b1,b2)}
++ is an internal subroutine, exported only for developement.
branchIfCan: (LP,TS,LP,B,B,B,B) -> Union(Branch,"failed")
++ \axiom{branchIfCan(leq,ts,lineq,b1,b2,b3,b4,b5)}
++ is an internal subroutine, exported only for developement.

```

=====
SquareFreeRegularSetDecompositionPackage examples
=====

```

A package providing a new algorithm for solving polynomial systems by means of regular chains. Two ways of solving are provided: in the sense of Zariski closure (like in Kalkbrenner's algorithm) or in the sense of the regular zeros (like in Wu, Wang or Lazard-Moreno methods). This algorithm is valid for any type of regular set. It does not care about the way a polynomial is added in a regular set, or how two quasi-components are compared (by an inclusion-test), or how the invertibility test is made in the tower of simple extensions associated with a regular set.

These operations are realized respectively by the domain TS and the packages QCMPPK(R,E,V,P,TS) and RSETGCD(R,E,V,P,TS).

The same way it does not care about the way univariate polynomial gcds (with coefficients in the tower of simple extensions associated with a regular set) are computed. The only requirement is that these gcds need to have invertible initials (normalized or not).

WARNING. There is no need for a user to call directly any operation of this package since they can be accessed by the domain \axiomType{TS}.

PACKAGE SRDCMPK SQUAREFREEREGULARSETDECOMPOSITIONPACKAGE3827

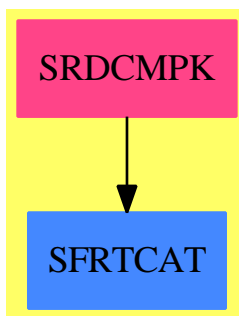

Thus, the operations of this package are not documented.

— package MATSTOR StorageEfficientMatrixOperations —

```

)abbrev package MATSTOR StorageEfficientMatrixOperations
++ Author: Clifton J. Williamson
++ Date Created: 18 July 1990
++ Date Last Updated: 18 July 1990
++ Description:
++ This package provides standard arithmetic operations on matrices.
++ The functions in this package store the results of computations
++ in existing matrices, rather than creating new matrices. This
++ package works only for matrices of type Matrix and uses the
++ internal representation of this type.

StorageEfficientMatrixOperations(R): Exports == Implementation where
R      : Ring
M      ==> Matrix R
NNI    ==> NonNegativeInteger
ARR    ==> PrimitiveArray R
REP    ==> PrimitiveArray PrimitiveArray R

Exports ==> with
copy_! : (M,M) -> M
++ \spad{copy!(c,a)} copies the matrix \spad{a} into the matrix c.
++ Error: if \spad{a} and c do not have the same
++ dimensions.
plus_! : (M,M,M) -> M
++ \spad{plus!(c,a,b)} computes the matrix sum \spad{a + b} and stores the
++ result in the matrix c.
++ Error: if \spad{a}, b, and c do not have the same dimensions.
minus_! : (M,M) -> M
++ \spad{minus!(c,a)} computes \spad{-a} and stores the result in the
++ matrix c.
++ Error: if a and c do not have the same dimensions.
minus_! : (M,M,M) -> M
++ \spad{!minus!(c,a,b)} computes the matrix difference \spad{a - b}
++ and stores the result in the matrix c.
++ Error: if \spad{a}, b, and c do not have the same dimensions.
leftScalarTimes_! : (M,R,M) -> M
++ \spad{leftScalarTimes!(c,r,a)} computes the scalar product
++ \spad{r * a} and stores the result in the matrix c.
++ Error: if \spad{a} and c do not have the same dimensions.
rightScalarTimes_! : (M,M,R) -> M
++ \spad{rightScalarTimes!(c,a,r)} computes the scalar product
++ \spad{a * r} and stores the result in the matrix c.
++ Error: if \spad{a} and c do not have the same dimensions.
times_! : (M,M,M) -> M
++ \spad{times!(c,a,b)} computes the matrix product \spad{a * b}
++ and stores the result in the matrix c.
++ Error: if \spad{a}, b, and c do not have
++ compatible dimensions.
power_! : (M,M,M,M,NNI) -> M
++ \spad{power!(a,b,c,m,n)} computes m ** n and stores the result in

```

```

++ \spad{a}. The matrices b and c are used to store intermediate results.
++ Error: if \spad{a}, b, c, and m are not square
++ and of the same dimensions.
"***" : (M,NNI) -> M
++ \spad{x ** n} computes the n-th power
++ of a square matrix. The power n is assumed greater than 1.

```

```
=====
StreamTaylorSeriesOperations examples
=====
```

StreamTaylorSeriesOperations implements Taylor series arithmetic, where a Taylor series is represented by a stream of its coefficients.

Problems raising a UTS to a negative integer power.

The code in `powern(rn,x)` which raises an unnecessary error where no distinction between rational and integer powers are made.

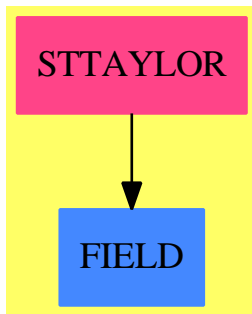

The fix is easy. Since the problem does not exist in SUPS we can just take the definition there.

L       ==> List
LA      ==> List A
YS      ==> Y$ParadoxicalCombinatorsForStreams(A)
UN      ==> Union(ST A,"failed")
Exports ==> with
"+"      : (ST A,ST A) -> ST A
++ a + b returns the power series sum of \spad{a} and \spad{b}:
++ \spad{[a0,a1,..] + [b0,b1,..] = [a0 + b0,a1 + b1,..]}
"-"      : (ST A,ST A) -> ST A
++ a - b returns the power series difference of \spad{a} and
++ \spad{b}: \spad{[a0,a1,..] - [b0,b1,..] = [a0 - b0,a1 - b1,..]}
"_"      : ST A -> ST A
++ - a returns the power series negative of \spad{a}:
++ \spad{- [a0,a1,..] = [- a0,- a1,..]}
"*"      : (ST A,ST A) -> ST A
++ a * b returns the power series (Cauchy) product of \spad{a} and b:
++ \spad{[a0,a1,..] * [b0,b1,..] = [c0,c1,..]} where
++ \spad{ck = sum(i + j = k,ai * bk)}.
"*"      : (A,ST A) -> ST A
++ r * a returns the power series scalar multiplication of r by \spad{a}:
++ \spad{r * [a0,a1,..] = [r * a0,r * a1,..]}
"*"      : (ST A,A) -> ST A

```

```

++ a * r returns the power series scalar multiplication of \spad{a} by r:
++ \spad{[a0,a1,...] * r = [a0 * r,a1 * r,...]}
"exquo"      : (ST A,ST A) -> Union(ST A,"failed")
++ exquo(a,b) returns the power series quotient of \spad{a} by b,
++ if the quotient exists, and "failed" otherwise
"/"         : (ST A,ST A) -> ST A
++ a / b returns the power series quotient of \spad{a} by b.
++ An error message is returned if \spad{b} is not invertible.
++ This function is used in fixed point computations.
recip       : ST A -> UN
++ recip(a) returns the power series reciprocal of \spad{a}, or
++ "failed" if not possible.
monom       : (A,I) -> ST A
++ monom(deg,coef) is a monomial of degree deg with coefficient
++ coef.
integers    : I -> ST I
++ integers(n) returns \spad{[n,n+1,n+2,...]}.
oddintegers : I -> ST I
++ oddintegers(n) returns \spad{[n,n+2,n+4,...]}.
int         : A -> ST A
++ int(r) returns [r,r+1,r+2,...], where r is a ring element.
mapmult     : (ST A,ST A) -> ST A
++ mapmult([a0,a1,..],[b0,b1,..])
++ returns \spad{[a0*b0,a1*b1,..]}.
deriv       : ST A -> ST A
++ deriv(a) returns the derivative of the power series with
++ respect to the power series variable. Thus
++ \spad{deriv([a0,a1,a2,...])} returns \spad{[a1,2 a2,3 a3,...]}.
gderiv      : (I -> A,ST A) -> ST A
++ gderiv(f,[a0,a1,a2,..]) returns
++ \spad{[f(0)*a0,f(1)*a1,f(2)*a2,..]}.
coerce      : A -> ST A
++ coerce(r) converts a ring element r to a stream with one element.
eval        : (ST A,A) -> ST A
++ eval(a,r) returns a stream of partial sums of the power series
++ \spad{a} evaluated at the power series variable equal to r.
compose     : (ST A,ST A) -> ST A
++ compose(a,b) composes the power series \spad{a} with
++ the power series b.
lagrange    : ST A -> ST A
++ lagrange(g) produces the power series for f where f is
++ implicitly defined as \spad{f(z) = z*g(f(z))}.
revert      : ST A -> ST A
++ revert(a) computes the inverse of a power series \spad{a}
++ with respect to composition.
++ the series should have constant coefficient 0 and first
++ order coefficient 1.
adddiag     : ST ST A -> ST A
++ adddiag(x) performs diagonal addition of a stream of streams. if x =
++ \spad{[[a<0,0>,a<0,1>,..],[a<1,0>,a<1,1>,..],[a<2,0>,a<2,1>,..],..]}

```

```

++ and \spad{adddiag(x) = [b<0,b<1>,...], then b<k> = sum(i+j=k,a<i,j>)}.
lambert      : ST A -> ST A
++ lambert(st) computes \spad{f(x) + f(x**2) + f(x**3) + ...}
++ if st is a stream representing \spad{f(x)}.
++ This function is used for computing infinite products.
++ If \spad{f(x)} is a power series with constant coefficient 1 then
++ \spad{prod(f(x**n),n = 1..infinity) = exp(lambert(log(f(x))))}.
oddlambert   : ST A -> ST A
++ oddlambert(st) computes \spad{f(x) + f(x**3) + f(x**5) + ...}
++ if st is a stream representing \spad{f(x)}.
++ This function is used for computing infinite products.
++ If f(x) is a power series with constant coefficient 1 then
++ \spad{prod(f(x**(2*n-1)),n=1..infinity) = exp(oddlambert(log(f(x))))}.
evenlambert  : ST A -> ST A
++ evenlambert(st) computes \spad{f(x**2) + f(x**4) + f(x**6) + ...}
++ if st is a stream representing \spad{f(x)}.
++ This function is used for computing infinite products.
++ If \spad{f(x)} is a power series with constant coefficient 1, then
++ \spad{prod(f(x**(2*n)),n=1..infinity) = exp(evenlambert(log(f(x))))}.
generallambert : (ST A,I,I) -> ST A
++ generallambert(f(x),a,d) returns
++ \spad{f(x**a) + f(x**(a + d)) + f(x**(a + 2 d)) + ...}.
++ \spad{f(x)} should have zero constant
++ coefficient and \spad{a} and d should be positive.
multisect    : (I,I,ST A) -> ST A
++ multisect(a,b,st)
++ selects the coefficients of \spad{x**((a+b)*n+a)},
++ and changes them to \spad{x**n}.
invmultisect : (I,I,ST A) -> ST A
++ invmultisect(a,b,st) substitutes \spad{x**((a+b)*n)} for \spad{x**n}
++ and multiplies by \spad{x**b}.
if A has Algebra RN then
integrate    : (A,ST A) -> ST A
++ integrate(r,a) returns the integral of the power series \spad{a}
++ with respect to the power series variable integration where
++ r denotes the constant of integration. Thus
++ \spad{integrate(a,[a0,a1,a2,...]) = [a,a0,a1/2,a2/3,...]}.
lazyIntegrate : (A,( ) -> ST A) -> ST A
++ lazyIntegrate(r,f) is a local function
++ used for fixed point computations.
nlde         : ST ST A -> ST A
++ nlde(u) solves a
++ first order non-linear differential equation described by u of the
++ form \spad{[[b<0,0>,b<0,1>,...],[b<1,0>,b<1,1>,...]}
++ the differential equation has the form
++ \spad{y'=sum(i=0 to infinity,j=0 to infinity,b<i,j>*(x**i)*(y**j))}.
powern      : (RN,ST A) -> ST A
++ powern(r,f) raises power series f to the power r.
if A has Field then
mapdiv      : (ST A,ST A) -> ST A

```

```

    ++ mapdiv([a0,a1,..],[b0,b1,..]) returns
    ++ \spad{[a0/b0,a1/b1,..]}.
lazyGintegrate : (I -> A,A,() -> ST A) -> ST A
    ++ lazyGintegrate(f,r,g) is used for fixed point computations.
power          : (A,ST A) -> ST A
    ++ power(a,f) returns the power series f raised to the power \spad{a}.

public ==> with
  -- what we really want to have here is a matrix over
  -- linear polynomials in the list of symbols, having arbitrary
  -- coefficients from a ring extension of R, e.g. FRAC POLY R.
  structuralConstants : (L S, M FRAC POLY R) -> V M FRAC POLY R
  ++ structuralConstants(ls,mt) determines the structural constants
  ++ of an algebra with generators ls and multiplication table mt, the
  ++ entries of which must be given as linear polynomials in the
  ++ indeterminates given by ls. The result is in particular useful
  ++ as fourth argument for \spadtype{AlgebraGivenByStructuralConstants}

```

```

++ and \spadtype{GenericNonAssociativeAlgebra}.
structuralConstants : (L S, M POLY R) -> V M POLY R
++ structuralConstants(ls,mt) determines the structural constants
++ of an algebra with generators ls and multiplication table mt, the
++ entries of which must be given as linear polynomials in the
++ indeterminates given by ls. The result is in particular useful
++ as fourth argument for \spadtype{AlgebraGivenByStructuralConstants}
++ and \spadtype{GenericNonAssociativeAlgebra}.
structuralConstants: L M R -> V M R
++ structuralConstants(basis) takes the basis of a matrix
++ algebra, e.g. the result of \spadfun{basisOfCentroid} and calculates
++ the structural constants.
++ Note, that the it is not checked, whether basis really is a
++ basis of a matrix algebra.
coordinates: (M R, L M R) -> V R
++ coordinates(a,[v1,...,vn]) returns the coordinates of \spad{a}
++ with respect to the \spad{R}-module basis \spad{v1},..., \spad{vn}.

Symbolic solver for systems of rational functions with coefficients in an integral domain R.

The systems are solved in the field of rational functions over R. Solutions are exact of the form variable = value when the value is a member of the coefficient domain R. Otherwise the solutions are implicitly expressed as roots of univariate polynomial equations over R.

Care is taken to guarantee that the denominators of the input equations do not vanish on the solution sets.

The arguments to solve can either be given as equations or as rational

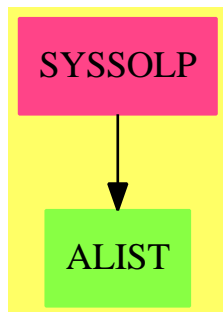

functions interpreted as equal to zero. The user can specify an explicit list of symbols to be solved for, treating all other symbols appearing as parameters or omit the list of symbols in which case the system tries to solve with respect to all symbols appearing in the input.

solve: (L F, L SE) -> L L EQ F
++ solve(lp,lv) finds the solutions of the list lp of
++ rational functions with respect to the list of symbols lv.

solve: (L EQ F, L SE) -> L L EQ F
++ solve(le,lv) finds the solutions of the
++ list le of equations of rational functions
++ with respect to the list of symbols lv.

solve: L F -> L L EQ F
++ solve(lp) finds the solutions of the list lp of rational
++ functions with respect to all symbols appearing in lp.

solve: L EQ F -> L L EQ F
++ solve(le) finds the solutions of the list le of equations of
++ rational functions with respect to all symbols appearing in le.

solve: (F, SE) -> L EQ F
++ solve(p,v) solves the equation p=0, where p is a rational function
++ with respect to the variable v.

solve: (EQ F,SE) -> L EQ F
++ solve(eq,v) finds the solutions of the equation
++ eq with respect to the variable v.

solve: F -> L EQ F
++ solve(p) finds the solution of a rational function p = 0

```

```

++ with respect to the unique variable appearing in p.

solve:      EQ F      -> L EQ F
++ solve(eq) finds the solutions of the equation eq
++ with respect to the unique variable appearing in eq.

triangularSystems: (L F,      L SE) -> L L P R
++ triangularSystems(lf,lv) solves the system of equations
++ defined by lf with respect to the list of symbols lv;
++ the system of equations is obtained
++ by equating to zero the list of rational functions lf.
++ The output is a list of solutions where
++ each solution is expressed as a "reduced" triangular system of
++ polynomials.

--    IS THERE A WORKING DOMAIN Tableau ??
--    coerce : M I -> Tableau(I)
--    ++ coerce(ytab) coerces the Young-Tableau ytab to an element of
--    ++ the domain Tableau(I).

coleman : (L I, L I, L I) -> M I
++ coleman(alpha,beta,pi):
++ there is a bijection from the set of matrices having nonnegative
++ entries and row sums alpha, column sums beta
++ to the set of  $S_{\alpha} - S_{\beta}$  double cosets of the
++ symmetric group  $S_n$ . ( $S_{\alpha}$  is the Young subgroup
++ corresponding to the improper partition alpha).
++ For a representing element pi of such a double coset,
++ coleman(alpha,beta,pi) generates the Coleman-matrix
++ corresponding to alpha, beta, pi.
++ Note that The permutation pi of  $\{1,2,\dots,n\}$  has to be given
++ in list form.
++ Note that the inverse of this map is inverseColeman
++ (if pi is the lexicographical smallest permutation
++ in the coset). For details see James/Kerber.
inverseColeman : (L I, L I, M I) -> L I
++ inverseColeman(alpha,beta,C):
++ there is a bijection from the set of matrices having nonnegative
++ entries and row sums alpha, column sums beta
++ to the set of  $S_{\alpha} - S_{\beta}$  double cosets of the
++ symmetric group  $S_n$ . ( $S_{\alpha}$  is the Young subgroup
++ corresponding to the improper partition alpha).
++ For such a matrix C, inverseColeman(alpha,beta,C)
++ calculates the lexicographical smallest pi in the
++ corresponding double coset.
++ Note that the resulting permutation pi of  $\{1,2,\dots,n\}$ 
++ is given in list form.
++ Notes: the inverse of this map is coleman.
++ For details, see James/Kerber.
listYoungTableaus : (L I) -> L M I
++ listYoungTableaus(lambda) where lambda is a proper partition
++ generates the list of all standard tableaus of shape lambda
++ by means of lattice permutations. The numbers of the lattice
++ permutation are interpreted as column labels. Hence the
++ contents of these lattice permutations are the conjugate of
++ lambda.
++ Notes: the functions nextLatticePermutation and

```

```

++ makeYoungTableau are used.
++ The entries are from 0,...,n-1.
makeYoungTableau : (L I,L I) -> M I
++ makeYoungTableau(lambda,gitter) computes for a given lattice
++ permutation gitter and for an improper partition lambda
++ the corresponding standard tableau of shape lambda.
++ Notes: see listYoungTableaus.
++ The entries are from 0,...,n-1.
nextColeman : (L I, L I, M I) -> M I
++ nextColeman(alpha,beta,C) generates the next Coleman matrix
++ of column sums alpha and row sums beta according
++ to the lexicographical order from bottom-to-top.
++ The first Coleman matrix is achieved by C=new(1,1,0).
++ Also, new(1,1,0) indicates that C is the last Coleman matrix.
nextLatticePermutation : (L I, L I, B) -> L I
++ nextLatticePermutation(lambda,lattP,constructNotFirst) generates
++ the lattice permutation according to the proper partition
++ lambda succeeding the lattice permutation lattP in
++ lexicographical order as long as constructNotFirst is true.
++ If constructNotFirst is false, the first lattice permutation
++ is returned.
++ The result nil indicates that lattP has no successor.
nextPartition : (V I, V I, I) -> V I
++ nextPartition(gamma,part,number) generates the partition of
++ number which follows part according to the right-to-left
++ lexicographical order. The partition has the property that
++ its components do not exceed the corresponding components of
++ gamma. The first partition is achieved by part=[].
++ Also, [] indicates that part is the last partition.
nextPartition : (L I, V I, I) -> V I
++ nextPartition(gamma,part,number) generates the partition of
++ number which follows part according to the right-to-left
++ lexicographical order. The partition has the property that
++ its components do not exceed the corresponding components of
++ gamma. the first partition is achieved by part=[].
++ Also, [] indicates that part is the last partition.
numberOfImproperPartitions: (I,I) -> I
++ numberOfImproperPartitions(n,m) computes the number of partitions
++ of the nonnegative integer n in m nonnegative parts with regarding
++ the order (improper partitions).
++ Example: numberOfImproperPartitions (3,3) is 10,
++ since [0,0,3], [0,1,2], [0,2,1], [0,3,0], [1,0,2], [1,1,1],
++ [1,2,0], [2,0,1], [2,1,0], [3,0,0] are the possibilities.
++ Note that this operation has a recursive implementation.
subSet : (I,I,I) -> L I
++ subSet(n,m,k) calculates the k-th m-subset of the set
++ 0,1,...,(n-1) in the lexicographic order considered as
++ a decreasing map from 0,...,(m-1) into 0,...,(n-1).
++ See S.G. Williamson: Theorem 1.60.
++ Error: if not (0 <= m <= n and 0 <= k < (n choose m)).

```

```

unrankImproperPartitions0 : (I,I,I) -> L I
  ++ unrankImproperPartitions0(n,m,k) computes the k-th improper
  ++ partition of nonnegative n in m nonnegative parts in reverse
  ++ lexicographical order.
  ++ Example: [0,0,3] < [0,1,2] < [0,2,1] < [0,3,0] <
  ++ [1,0,2] < [1,1,1] < [1,2,0] < [2,0,1] < [2,1,0] < [3,0,0].
  ++ Error: if k is negative or too big.
  ++ Note that counting of subtrees is done by
  ++ numberOfImproperPartitions
unrankImproperPartitions1: (I,I,I) -> L I
  ++ unrankImproperPartitions1(n,m,k) computes the k-th improper
  ++ partition of nonnegative n in at most m nonnegative parts
  ++ ordered as follows: first, in reverse
  ++ lexicographically according to their non-zero parts, then
  ++ according to their positions (i.e. lexicographical order
  ++ using subSet: [3,0,0] < [0,3,0] < [0,0,3] < [2,1,0] <
  ++ [2,0,1] < [0,2,1] < [1,2,0] < [1,0,2] < [0,1,2] < [1,1,1].
  ++ Note that counting of subtrees is done by
  ++ numberOfImproperPartitionsInternal.

TaylorSolve examples
=====
```

UTSSOL is a facility to compute the first few coefficients of a Taylor series given only implicitly by a function f that vanishes when applied to the Taylor series.

It uses the method of undetermined coefficients.

Could I either  
 take a function UTSCAT F  $\$ \rightarrow \$$  UTSCAT F and still be able to compute  
 with undetermined coefficients, or  
 take a function F  $\$ \rightarrow \$$  F, and do likewise?

Let's see.

Try to compute the equation without resorting to power series. I.e., %  
 c: SUP SUP F, and f: SUP SUP F  $\$ \rightarrow \$$  SUP SUP F. Won't this make the  
 computation of coefficients terribly slow?

I could also try to replace transcendental kernels with variables\dots

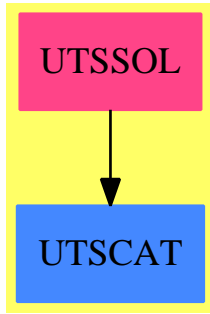

Unfortunately, SUP F does not have TRANFUN -- well, it can't, of course. However, I'd like to be able to compute %  
 sin(1+monomial(1,1)\$UFPS SUP EXPR INT).

## TaylorSolve (UTSSOL)

**Exports:**  
seriesSolve

— package UTSSOL TaylorSolve —

```

)abbrev package UTSSOL TaylorSolve
++ Description:
++ This package has no description

TaylorSolve(F, UTSF, UTSSUPF): Exports == Implementation where
  F: Field
  SUP ==> SparseUnivariatePolynomialExpressions
  UTSF: UnivariateTaylorSeriesCategory F
  UTSSUPF: UnivariateTaylorSeriesCategory SUP F
  NNI ==> NonNegativeInteger

Exports == with
  seriesSolve: (UTSSUPF -> UTSSUPF, List F) -> UTSF

Implementation == add
\getchunk{implementation: UTSSOL TaylorSolve}

```

— implementation: UTSSOL TaylorSolve —

```

seriesSolve(f, l) ==
  c1 :=
  map((x:F):SUP F +-> x::(SUP F), l)
  $ListFunctions2(F, SUP F)::(Stream SUP F)
  coeffs: Stream SUP F := concat(c1, generate(mononial(1$F,1$NNI)))

```

```
--          coeffs: Stream SUP F := concat(c1, monomial(1$F,1$NNI))
```

---

coeffs is the stream of the already computed coefficients of the solution, plus one which is so far undetermined. We store in st.2 the complete stream and in st.1 the stream starting with the first coefficient that has possibly not yet been computed.

The mathematics is not quite worked out. If coeffs is initialized as stream with all coefficients set to the `\emph{same}` transcendental value, and not enough initial values are given, then the missing ones are implicitly assumed to be all identical. It may well happen that a solution is produced, although it is not uniquely determined\dots

— implementation: UTSSOL TaylorSolve —

```
st: List Stream SUP F := [coeffs, coeffs]
```

---

Consider an arbitrary equation  $f(x, y(x)) = 0$ . When setting  $x = 0$ , we obtain  $f(0, y(0)) = 0$ . It is not necessarily the case that this determines  $y(0)$  uniquely, so we need one initial value that satisfies this equation.

`seriesSolve` should check that the given initial values satisfy  $f(0, y(0), y'(0), \dots) = 0$ .

Now consider the derivatives of  $f$ , where we write  $y$  instead of  $y(x)$  for better readability:

$$\frac{d}{dx} f(x, y) = f_1(x, y) + f_2(x, y)y'$$

and

$$\begin{aligned} \frac{d^2}{dx^2} f(x, y) &= f_{1,1}(x, y) \\ &+ f_{1,2}(x, y)y' \\ &+ f_{2,1}(x, y)y' \\ &+ f_{2,2}(x, y)(y')^2 \\ &+ f_2(x, y)y'' \end{aligned}$$

In general,  $\frac{d^2}{dx^2} f(x, y)$  depends only linearly on  $y''$ .

This points to another possibility: Since we know that we only need to solve linear equations, we could compute two values and then use interpolation. This might be a bit slower, but more importantly: can we still check that we have enough initial values? Furthermore, we then really need that  $f$  is analytic, i.e., operators are not necessarily allowed anymore. However, it seems that composition is allowed.

— implementation: UTSSOL TaylorSolve —

```
next: () -> F :=
  nr := st.1
  res: F

  if ground?(coeff: SUP F := nr.1)$(SUP F)
```

If the next element was already calculated, we can simply return it:

— implementation: UTSSOL TaylorSolve —

```
then
  res := ground coeff
  st.1 := rest nr
else
```

Otherwise, we have to find the first non-satisfied relation and solve it. It should be linear, or a single non-constant monomial. That is, the solution should be unique.

— implementation: UTSSOL TaylorSolve —

```
ns := st.2
eqs: Stream SUP F := coefficients f series ns
while zero? first eqs repeat eqs := rest eqs
eq: SUP F := first eqs
if degree eq > 1 then
  if monomial? eq then res := 0
  else
    output(hconcat("The equation is: ", eq::OutputForm))
    $OutputPackage
    error "seriesSolve: equation for coefficient not linear"
else res := (-coefficient(eq, 0$NNI)$(SUP F)
  /coefficient(eq, 1$NNI)$(SUP F))

nr.1 := res::SUP F
-- concat!(st.2, monomial(1$F,1$NNI))
st.1 := rest nr

res

```

Implementation ==> add

---

I have had to work my way around the following bug in the compiler: When a local variable is given a mapping as a value, e.g.

```
foo : SF -> SF := makeFloatFunction(f,t),
```

the compiler cannot distinguish that local variable from a local function defined elsewhere in the package. Thus, when 'foo' is passed to a function, e.g.

```
bird := fcn(foo),
```

foo will often be compiled as DRAW;foo rather than foo. This, of course, causes a run-time error.

To avoid this problem, local variables are not given mappings as values, but rather (single-ton) lists of mappings. The first element of the list can always be extracted and everything

goes through as before. There is no major loss in efficiency, as the computation of points will always dominate the computation time.

—————

The function `myTrap1` is a local function for used in creating maps `SF -> Point SF` (two dimensional). The range of this function is `SingleFloat`. As originally coded it would return `$NaNvalue$Lisp` which is outside the range. Since this function is only used internally by the draw package we handle the “failed” case by returning zero. We handle the out-of-range case by returning the maximum or minimum `SingleFloat` value.

## TopLevelDrawFunctionsForPoints (DRAWPT)

**Exports:**

draw

— package DRAWPT TopLevelDrawFunctionsForPoints —

```

)abbrev package DRAWPT TopLevelDrawFunctionsForPoints
++ Author: Mike Dewar
++ Date Created: 24 May 1995
++ Date Last Updated: 25 November 1996
++ Description:
++ TopLevelDrawFunctionsForPoints provides top level functions
++ for drawing curves and surfaces described by sets of points.

TopLevelDrawFunctionsForPoints(): Exports == Implementation where

DROP ==> DrawOption
L ==> List
SF ==> DoubleFloat
Pt ==> Point SF
VIEW2 ==> TwoDimensionalViewport
VIEW3 ==> ThreeDimensionalViewport

Exports ==> with
draw: (L SF,L SF) -> VIEW2
  ++ draw(lx,ly) plots the curve constructed of points (x,y) for x
  ++ in \spad{lx} for y in \spad{ly}.
draw: (L SF,L SF,L DROP) -> VIEW2
  ++ draw(lx,ly,l) plots the curve constructed of points (x,y) for x
  ++ in \spad{lx} for y in \spad{ly}.
  ++ The options contained in the list l of
  ++ the domain \spad{DrawOption} are applied.
draw: (L Pt) -> VIEW2
  ++ draw(lp) plots the curve constructed from the list of points lp.
draw: (L Pt,L DROP) -> VIEW2
  ++ draw(lp,l) plots the curve constructed from the list of points lp.

```

```

++ The options contained in the list l of the domain \spad{DrawOption}
++ are applied.
draw: (L SF, L SF, L SF) -> VIEW3
++ draw(lx,ly,lz) draws the surface constructed by projecting the values
++ in the \axiom{lz} list onto the rectangular grid formed by the
++ \axiom{lx x ly}.
draw: (L SF, L SF, L SF, L DROP) -> VIEW3
++ draw(lx,ly,lz,l) draws the surface constructed by
++ projecting the values
++ in the \axiom{lz} list onto the rectangular grid formed by the
++ The options contained in the list l of the domain \spad{DrawOption}
++ are applied.

```

Implementation ==> add

Exports ==> with
  expand      : F -> F
    ++ expand(f) performs the following expansions on f:\begin{items}
    ++ \item 1. logs of products are expanded into sums of logs,
    ++ \item 2. trigonometric and hyperbolic trigonometric functions
    ++ of sums are expanded into sums of products of trigonometric
    ++ and hyperbolic trigonometric functions.
    ++ \item 3. formal powers of the form \spad{(a/b)**c} are expanded into
    ++ \spad{a**c * b**(-c)}.
    ++ \end{items}
  simplify   : F -> F
    ++ simplify(f) performs the following simplifications on f:\begin{items}
    ++ \item 1. rewrites trigs and hyperbolic trigs in terms
    ++ of \spad{sin} ,\spad{cos}, \spad{sinh}, \spad{cosh}.
    ++ \item 2. rewrites \spad{sin**2} and \spad{sinh**2} in terms
    ++ of \spad{cos} and \spad{cosh},
    ++ \item 3. rewrites \spad{exp(a)*exp(b)} as \spad{exp(a+b)}.
    ++ \item 4. rewrites \spad{(a**(1/n))**m * (a**(1/s))**t} as a single
    ++ power of a single radical of \spad{a}.
    ++ \end{items}
  htrigs     : F -> F
    ++ htrigs(f) converts all the exponentials in f into
    ++ hyperbolic sines and cosines.
  simplifyExp: F -> F
    ++ simplifyExp(f) converts every product \spad{exp(a)*exp(b)}
    ++ appearing in f into \spad{exp(a+b)}.
  simplifyLog : F -> F
    ++ simplifyLog(f) converts every \spad{log(a) - log(b)} appearing in f
    ++ into \spad{log(a/b)}, every \spad{log(a) + log(b)} into \spad{log(a*b)}
    ++ and every \spad{n*log(a)} into \spad{log(a^n)}.
  expandPower: F -> F
    ++ expandPower(f) converts every power \spad{(a/b)**c} appearing
    ++ in f into \spad{a**c * b**(-c)}.
  expandLog   : F -> F
    ++ expandLog(f) converts every \spad{log(a/b)} appearing in f into
    ++ \spad{log(a) - log(b)}, and every \spad{log(a*b)} into
    ++ \spad{log(a) + log(b)}..

```

```

cos2sec      : F -> F
  ++ cos2sec(f) converts every \spad{cos(u)} appearing in f into
  ++ \spad{1/sec(u)}.
cosh2sech   : F -> F
  ++ cosh2sech(f) converts every \spad{cosh(u)} appearing in f into
  ++ \spad{1/sech(u)}.
cot2trig    : F -> F
  ++ cot2trig(f) converts every \spad{cot(u)} appearing in f into
  ++ \spad{cos(u)/sin(u)}.
coth2trigh  : F -> F
  ++ coth2trigh(f) converts every \spad{coth(u)} appearing in f into
  ++ \spad{cosh(u)/sinh(u)}.
csc2sin     : F -> F
  ++ csc2sin(f) converts every \spad{csc(u)} appearing in f into
  ++ \spad{1/sin(u)}.
csch2sinh   : F -> F
  ++ csch2sinh(f) converts every \spad{csch(u)} appearing in f into
  ++ \spad{1/sinh(u)}.
sec2cos     : F -> F
  ++ sec2cos(f) converts every \spad{sec(u)} appearing in f into
  ++ \spad{1/cos(u)}.
sech2cosh   : F -> F
  ++ sech2cosh(f) converts every \spad{sech(u)} appearing in f into
  ++ \spad{1/cosh(u)}.
sin2csc     : F -> F
  ++ sin2csc(f) converts every \spad{sin(u)} appearing in f into
  ++ \spad{1/csc(u)}.
sinh2csch   : F -> F
  ++ sinh2csch(f) converts every \spad{sinh(u)} appearing in f into
  ++ \spad{1/csch(u)}.
tan2trig    : F -> F
  ++ tan2trig(f) converts every \spad{tan(u)} appearing in f into
  ++ \spad{sin(u)/cos(u)}.
tanh2trigh  : F -> F
  ++ tanh2trigh(f) converts every \spad{tanh(u)} appearing in f into
  ++ \spad{sinh(u)/cosh(u)}.
tan2cot     : F -> F
  ++ tan2cot(f) converts every \spad{tan(u)} appearing in f into
  ++ \spad{1/cot(u)}.
tanh2coth   : F -> F
  ++ tanh2coth(f) converts every \spad{tanh(u)} appearing in f into
  ++ \spad{1/coth(u)}.
cot2tan     : F -> F
  ++ cot2tan(f) converts every \spad{cot(u)} appearing in f into
  ++ \spad{1/tan(u)}.
coth2tanh   : F -> F
  ++ coth2tanh(f) converts every \spad{coth(u)} appearing in f into
  ++ \spad{1/tanh(u)}.
removeCosSq: F -> F
  ++ removeCosSq(f) converts every \spad{cos(u)**2} appearing in f into

```

```

    ++ \spad{1 - sin(x)**2}, and also reduces higher
    ++ powers of \spad{cos(u)} with that formula.
removeSinSq: F -> F
    ++ removeSinSq(f) converts every \spad{sin(u)**2} appearing in f into
    ++ \spad{1 - cos(x)**2}, and also reduces higher powers of
    ++ \spad{sin(u)} with that formula.
removeCoshSq:F -> F
    ++ removeCoshSq(f) converts every \spad{cosh(u)**2} appearing in f into
    ++ \spad{1 - sinh(x)**2}, and also reduces higher powers of
    ++ \spad{cosh(u)} with that formula.
removeSinhSq:F -> F
    ++ removeSinhSq(f) converts every \spad{sinh(u)**2} appearing in f into
    ++ \spad{1 - cosh(x)**2}, and also reduces higher powers
    ++ of \spad{sinh(u)} with that formula.
if R has PatternMatchable(R) and R has ConvertibleTo(Pattern(R))
and F has ConvertibleTo(Pattern(R)) and F has PatternMatchable R then
expandTrigProducts : F -> F
    ++ expandTrigProducts(e) replaces \axiom{sin(x)*sin(y)} by
    ++ \spad{(cos(x-y)-cos(x+y))/2}, \axiom{cos(x)*cos(y)} by
    ++ \spad{(cos(x-y)+cos(x+y))/2}, and \axiom{sin(x)*cos(y)} by
    ++ \spad{(sin(x-y)+sin(x+y))/2}. Note that this operation uses
    ++ the pattern matcher and so is relatively expensive. To avoid
    ++ getting into an infinite loop the transformations are applied
    ++ at most ten times.

```

## The htrigs function

The htrigs function can be used to replace and reduce hyperbolic trigonometric identities.

The identity for  $\sinh(x)$  is  $(\exp(x) - \exp(-x))/2$

If we difference these we should get zero

$$f := \sinh(x) - (\exp(x) - \exp(-x))/2$$

instead, by default, we get

$$\frac{2\sinh(x) - \%e^x + \%e^{-x}}{2}$$

The function htrigs(f) gives 0

This works as follows:

```
m:=mainKernel f => sinh(x)
      Type: Union(Kernel(Expression(Integer)),...)
```

which is coerced to the first part of the union:

```
k:=m::Kernel(Expression(Integer))
```

and the operator is extracted:

```
op:=operator(k) => sinh
      Type: BasicOperator
```

The argument function extracts the variable used as arguments:

```
argument k ==> [x]
      Type Kernel(Expression(Integer))
```

At this point we have picked apart the main Kernel into its operator and its arguments. We now process the list of arguments.

The function htrigs is called on every element of the argument list, which in this case, returns a list:

```
arg:=[htrigs x for x in argument k]$List(Expression(Integer))
      => [x]
      Type: List(Expression(Integer))
```

We form a polynomial by replacing the kernel in the numerator with ?

```
num := univariate( numer f, k)

      x      -x
2? - %e  + %e
      Type: SparseUnivariatePolynomial(
          SparseMultivariatePolynomial(
              Integer, Kernel(Expression(Integer))))
```

and a polynomial of the denominator, replacing the kernel

```
den := univariate( denom f, k)

      2
      Type: SparseUnivariatePolynomial(
          SparseMultivariatePolynomial(
              Integer, Kernel(Expression(Integer))))
```

In this case the op is not the exponential so we are doing straight trig substitution. We reconstruct the function call using the op and arg values, that is:

```
g1 := op arg ==> sinh(x)
      Type: Expression(Integer)
```

So sup2htrigs, which is a local function, is used to simplify the parts of the fraction. In this case,

```
sup2htrigs(num, g1:= op arg) ==> 0
      Type: Expression(Integer)

sup2htrigs(den, g1) ==> 2
      Type: Expression(Integer)
```

Thus, the result is 0

The identity for  $\cosh(x)$  is  $(\exp(x) + \exp(-x))/2$

If we difference these we should get zero

```
f := cosh(x) - (%e^x + %e^-x)/2
```

instead, by default, we get

$$\frac{-e^x + e^{-x} + 2\cosh(x)}{2}$$

and the function call  $htrigs(f)$  gives 0

This works as follows:

```

m:=mainKernel f => %ex
Type: Union(Kernel(Expression(Integer)),...)

```

which is coerced to the first part of the union:

```

k:=m::Kernel(Expression(Integer)) => %ex
Type: Kernel(Expression(Integer))

```

and the operator is extracted:

```

op:=operator(k) => exp
Type: BasicOperator

```

The argument function extracts the variable used as arguments:

```

argument k ==> [x]
Type Kernel(Expression(Integer))

```

At this point we have picked apart the main Kernel into its operator and its arguments. We now process the list of arguments.

The htrigs function is called on every element of the argument list, which in this case, returns a list:

```

arg:=[htrigs x for x in argument k]$List(Expression(Integer))
=> [x]
Type: List(Expression(Integer))

```

We form polynomial by replacing the kernel in the numerator with ?

```

num := univariate(numer f, k)
- ? - %e-x + 2cosh(x)
Type: SparseUnivariatePolynomial(
SparseMultivariatePolynomial(
Integer, Kernel(Expression(Integer))))

```

and a polynomial of the denominator, replacing the kernel

```

den := univariate(denom f, k)
2
Type: SparseUnivariatePolynomial(
SparseMultivariatePolynomial(
Integer, Kernel(Expression(Integer))))

```

In this case, the expression

```
is?(op, "exp"::Symbol) => true
```

so we form

```
a := first arg => x
      Type: Expression(Integer)
```

since we know that

```
cosh(x)+sinh(x) => %ex
```

we can form this use this expression in substitutions

```
g1 := cosh(a)+sinh(a) => sinh(x)+cosh(x)
      Type: Expression(Integer)
```

since we know that

```
cosh(x)-sinh(x) => - %e-x
```

we can form this use this expression in substitutions

```
g2 := cosh(a)-sinh(a) => -sinh(x)+cosh(x)
      Type: Expression(Integer)
```

```
b := (degree num)::Integer quo 2 => 0
      Type: NonNegativeInteger
```

The supexp function is using the g1 and g2 identities to replace exp(x)

```
supexp(num,g1,g2,b) => sinh(x)-cosh(x)-sinh(x)+2cosh(x)-cosh(x)
      Type: Expression(Integer)
```

```
supexp(den,g1,g2,b) => 2
      Type: Expression(Integer)
```

which is effectively

```
t1/t2 => (sinh(x)-cosh(x)-sinh(x)+2cosh(x)-cosh(x))/2
      Type: Expression(Integer)
```

the last form of which can be rearranged as:

```
(sinh(x)-sinh(x) + 2cosh(x)-cosh(x)-cosh(x) )/2 => 0
```

so the result is 0

## TranscendentalRischDESystem (RDETRS)

### Exports:

baseRDEsys monomRDEsys

— package RDETRS TranscendentalRischDESystem —

```

)abbrev package RDETRS TranscendentalRischDESystem
++ Author: Manuel Bronstein
++ Date Created: 17 August 1992
++ Date Last Updated: 3 February 1994
++ Description:
++ Risch differential equation system, transcendental case.

TranscendentalRischDESystem(F, UP): Exports == Implementation where
  F : Join(Field, CharacteristicZero, RetractableTo Integer)
  UP : UnivariatePolynomialCategory F

N ==> NonNegativeInteger
Z ==> Integer
RF ==> Fraction UP
V ==> Vector UP
U ==> Union(List UP, "failed")
REC ==> Record(z1:UP, z2:UP, r1:UP, r2:UP)

Exports ==> with
  monomRDEsys: (RF, RF, RF, UP -> UP) -> _
    Union(Record(a:UP, b:RF, h:UP, c1:RF, c2:RF, t:UP), "failed")
  ++ monomRDEsys(f,g1,g2,D) returns \spad{[A, B, H, C1, C2, T]} such that
  ++ \spad{(y1', y2') + ((0, -f), (f, 0)) (y1,y2) = (g1,g2)} has a solution
  ++ if and only if \spad{y1 = Q1 / T, y2 = Q2 / T},
  ++ where \spad{B,C1,C2,Q1,Q2} have no normal poles and satisfy
  ++ A \spad{(Q1', Q2') + ((H, -B), (B, H)) (Q1,Q2) = (C1,C2)}
  ++ D is the derivation to use.
  baseRDEsys: (RF, RF, RF) -> Union(List RF, "failed")
  ++ baseRDEsys(f, g1, g2) returns fractions \spad{y_1.y_2} such that
  ++ \spad{(y1', y2') + ((0, -f), (f, 0)) (y1,y2) = (g1,g2)}
  
```

```

++ if \spad{y_1,y_2} exist, "failed" otherwise.

=====  
 TransSolvePackage examples  
 =====

This package tries to find solutions of equations of type Expression(R).

This means expressions involving transcendental, exponential, logarithmic and nthRoot functions.

After trying to transform different kernels to one kernel by applying several rules, it calls zerosOf for the SparseUnivariatePolynomial in the remaining kernel.

For example the expression

$$\sin(x)\cos(x)-2$$

will be transformed to

$$-2 \tan(x/2)**4 -2 \tan(x/2)**3 -4 \tan(x/2)**2 +2 \tan(x/2) -2$$

by using the function normalize and then to

$$-2 \tan(x)**2 + \tan(x) -2$$

with help of subsTan. This function tries to express the given function in terms of tan(x/2) to express in terms of tan(x).

Other examples are the expressions

$$\sqrt{x+1}+\sqrt{x+7}+1$$

$$\sqrt{\sin(x)}+1$$

$$\text{solve}(1/2*v*v*\cos(\text{theta}+\text{phi})*\cos(\text{theta}+\text{phi})+g*1*\cos(\text{phi})=g*1,\text{phi})$$

## TransSolvePackage (SOLVETRA)

**Exports:**

solve

— package SOLVETRA TransSolvePackage —

```

)abbrev package SOLVETRA TransSolvePackage
++ Author: W. Wiwianka, Martin Rubey
++ Date Created: Summer 1991
++ Date Last Changed: 9/91
++ Description:
++ This package tries to find solutions of equations of type Expression(R).
++ This means expressions involving transcendental, exponential, logarithmic
++ and nthRoot functions.
++ After trying to transform different kernels to one kernel by applying
++ several rules, it calls zerosOf for the SparseUnivariatePolynomial in
++ the remaining kernel.
++ For example the expression \spad{sin(x)*cos(x)-2} will be transformed to
++ \spad{-2 tan(x/2)**4 -2 tan(x/2)**3 -4 tan(x/2)**2 +2 tan(x/2) -2}
++ by using the function normalize and then to
++ \spad{-2 tan(x)**2 + tan(x) -2}
++ with help of subsTan. This function tries to express the given function
++ in terms of \spad{tan(x/2)} to express in terms of \spad{tan(x)} .
++ Other examples are the expressions \spad{sqrt(x+1)+sqrt(x+7)+1} or
++ \spad{sqrt(sin(x))+1} .

This package finds the function func3 where func1 and func2 are given and  $func1 = func3(func2)$  . If there is no solution then function func1 will be returned.

An example would be

func1:= 8\*X\*\*3+32\*X\*\*2-14\*X ::EXPR INT

and

func2:=2\*X ::EXPR INT

convert them via univariate to FRAC SUP EXPR INT and then the solution is

func3:=X\*\*3+X\*\*2-X

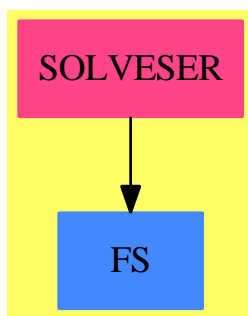

of type FRAC SUP EXPR INT

TriangularMatrixOperations examples
=====
```

This package provides functions that compute "fraction-free" inverses of upper and lower triangular matrices over a integral domain. By "fraction-free inverses" we mean the following: given a matrix B with entries in R and an element d of R such that  $d * \text{inv}(B)$  also has entries in R, we return  $d * \text{inv}(B)$ . Thus, it is not necessary to pass to the quotient field in any of our computations.

++ Author: Clifton J. Williamson
++ Date Created: Bastille Day 1989
++ Date Last Updated: 5 June 1990
++ Description:
++ Tools for constructing tubes around 3-dimensional parametric curves.

TubePlotTools(): Exports == Implementation where
  I ==> Integer
  SF ==> DoubleFloat
  L ==> List
  Pt ==> Point SF

Exports ==> with
  point: (SF,SF,SF,SF) -> Pt
    ++ point(x1,x2,x3,c) creates and returns a point from the three
    ++ specified coordinates \spad{x1}, \spad{x2}, \spad{x3}, and also
    ++ a fourth coordinate, c, which is generally used to specify the
    ++ color of the point.
  "*" : (SF,Pt) -> Pt
    ++ s * p returns a point whose coordinates are the scalar multiple
    ++ of the point p by the scalar s, preserving the color, or fourth
    ++ coordinate, of p.
  "+" : (Pt,Pt) -> Pt
    ++ p + q computes and returns a point whose coordinates are the sums
    ++ of the coordinates of the two points \spad{p} and \spad{q}, using
    ++ the color, or fourth coordinate, of the first point \spad{p}
    ++ as the color also of the point \spad{q}.
  "-" : (Pt,Pt) -> Pt
  
```

```

++ p - q computes and returns a point whose coordinates are the
++ differences of the coordinates of two points \spad{p} and \spad{q},
++ using the color, or fourth coordinate, of the first point \spad{p}
++ as the color also of the point \spad{q}.
dot : (Pt,Pt) -> SF
++ dot(p,q) computes the dot product of the two points \spad{p}
++ and \spad{q} using only the first three coordinates, and returns
++ the resulting \spadtype{DoubleFloat}.
cross : (Pt,Pt) -> Pt
++ cross(p,q) computes the cross product of the two points \spad{p}
++ and \spad{q} using only the first three coordinates, and keeping
++ the color of the first point p. The result is returned as a point.
unitVector: Pt -> Pt
++ unitVector(p) creates the unit vector of the point p and returns
++ the result as a point. Note that \spad{unitVector(p) = p/|p|}.
cosSinInfo: I -> L L SF
++ cosSinInfo(n) returns the list of lists of values for n, in the form
++ \spad{[[cos(n-1) a,sin(n-1) a],...,[cos 2 a,sin 2 a],[cos a,sin a]]}
++ where \spad{a = 2 pi/n}. Note that n should be greater than 2.
loopPoints: (Pt,Pt,Pt,SF,L L SF) -> L Pt
++ loopPoints(p,n,b,r,lls) creates and returns a list of points
++ which form the loop with radius r, around the center point
++ indicated by the point p, with the principal normal vector of
++ the space curve at point p given by the point(vector) n, and the
++ binormal vector given by the point(vector) b, and a list of lists,
++ lls, which is the \spadfun{cosSinInfo} of the number of points
++ defining the loop.

)abbrev package CLIP TwoDimensionalPlotClipping
++ Author: Clifton J. Williamson
++ Date Created: 22 December 1989
++ Date Last Updated: 10 July 1990
++ Description:
++ Automatic clipping for 2-dimensional plots
++ The purpose of this package is to provide reasonable plots of
++ functions with singularities.

TwoDimensionalPlotClipping(): Exports == Implementation where
B      ==> Boolean
L      ==> List
SEG    ==> Segment
RN     ==> Fraction Integer
SF     ==> DoubleFloat
Pt     ==> Point DoubleFloat
PLOT   ==> Plot
CLIPPED ==> Record(brans: L L Pt,xValues: SEG SF,yValues: SEG SF)

Exports ==> with
clip: PLOT -> CLIPPED
++ clip(p) performs two-dimensional clipping on a plot, p, from
++ the domain \spadtype{Plot} for the graph of one variable,
++ \spad{y = f(x)}; the default parameters \spad{1/4} for the fraction
++ and \spad{5/1} for the scale are used in the \spadfun{clip} function.

```

```

clip: (PLOT,RN,RN) -> CLIPPED
  ++ clip(p,frac,sc) performs two-dimensional clipping on a plot, p,
  ++ from the domain \spadtype{Plot} for the graph of one variable
  ++ \spad{y = f(x)}; the fraction parameter is specified by \spad{frac}
  ++ and the scale parameter is specified by \spad{sc} for use in the
  ++ \spadfun{clip} function.
clipParametric: PLOT -> CLIPPED
  ++ clipParametric(p) performs two-dimensional clipping on a plot,
  ++ p, from the domain \spadtype{Plot} for the parametric curve
  ++ \spad{x = f(t)}, \spad{y = g(t)}; the default parameters \spad{1/2}
  ++ for the fraction and \spad{5/1} for the scale are used in the
  ++ \fakeAxiomFun{iClipParametric} subroutine, which is called by this
  ++ function.
clipParametric: (PLOT,RN,RN) -> CLIPPED
  ++ clipParametric(p,frac,sc) performs two-dimensional clipping on a
  ++ plot, p, from the domain \spadtype{Plot} for the parametric curve
  ++ \spad{x = f(t)}, \spad{y = g(t)}; the fraction parameter is
  ++ specified by \spad{frac} and the scale parameter is specified
  ++ by \spad{sc} for use in the \fakeAxiomFun{iClipParametric} subroutine,
  ++ which is called by this function.
clipWithRanges: (L L Pt,SF,SF,SF,SF) -> CLIPPED
  ++ clipWithRanges(pointLists,xMin,xMax,yMin,yMax) performs clipping
  ++ on a list of lists of points, \spad{pointLists}. Clipping is
  ++ done within the specified ranges of \spad{xMin}, \spad{xMax} and
  ++ \spad{yMin}, \spad{yMax}. This function is used internally by
  ++ the \fakeAxiomFun{iClipParametric} subroutine in this package.
clip: L Pt -> CLIPPED
  ++ clip(l) performs two-dimensional clipping on a curve l, which is
  ++ a list of points; the default parameters \spad{1/2} for the
  ++ fraction and \spad{5/1} for the scale are used in the
  ++ \fakeAxiomFun{iClipParametric} subroutine, which is called by this
  ++ function.
clip: L L Pt -> CLIPPED
  ++ clip(ll) performs two-dimensional clipping on a list of lists
  ++ of points, \spad{ll}; the default parameters \spad{1/2} for
  ++ the fraction and \spad{5/1} for the scale are used in the
  ++ \fakeAxiomFun{iClipParametric} subroutine, which is called by this
  ++ function.

This package provides for square-free decomposition of univariate polynomials over arbitrary rings, i.e. a partial factorization such that each factor is a product of irreducibles with multiplicity one and the factors are pairwise relatively prime. If the ring has characteristic zero, the result is guaranteed to satisfy this condition. If the ring is an infinite ring of finite characteristic, then it may not be possible to decide when polynomials contain factors which are  $p$ th powers. In this case, the flag associated with that polynomial is set to "nil" (meaning that that polynomials are not guaranteed to be square-free).

## — package VECTOR2 VectorFunctions2 —

```
)abbrev package VECTOR2 VectorFunctions2
```

```
++ Description:
```

```
++ This package provides operations which all take as arguments
++ vectors of elements of some type \spad{A} and functions from \spad{A} to
++ another of type B. The operations all iterate over their vector argument
++ and either return a value of type B or a vector over B.
```

```
VectorFunctions2(A, B): Exports == Implementation where
  A, B: Type
```

```

VA ==> Vector A
VB ==> Vector B
O2 ==> FiniteLinearAggregateFunctions2(A, VA, B, VB)
UB ==> Union(B,"failed")

Exports ==> with
scan  : ((A, B) -> B, VA, B) -> VB
  ++ scan(func,vec,ident) creates a new vector whose elements are
  ++ the result of applying reduce to the binary function func,
  ++ increasing initial subsequences of the vector vec,
  ++ and the element ident.
reduce : ((A, B) -> B, VA, B) -> B
  ++ reduce(func,vec,ident) combines the elements in vec using the
  ++ binary function func. Argument ident is returned if vec is empty.
map    : (A -> B, VA) -> VB
  ++ map(f, v) applies the function f to every element of the vector v
  ++ producing a new vector containing the values.
map    : (A -> UB, VA) -> Union(VB,"failed")
  ++ map(f, v) applies the function f to every element of the vector v
  ++ producing a new vector containing the values or \spad{"failed"}.

Implementation ==> add

++ pointColorDefault() returns the default color of points in a 2D
++ viewport.

pointColorDefault  : PAL                                -> PAL
++ pointColorDefault(p) sets the default color of points in a 2D viewport
++ to the palette p.

lineColorDefault   : ()                                -> PAL
++ lineColorDefault() returns the default color of lines connecting
++ points in a 2D viewport.

lineColorDefault   : PAL                                -> PAL
++ lineColorDefault(p) sets the default color of lines connecting points
++ in a 2D viewport to the palette p.

axesColorDefault   : ()                                -> PAL
++ axesColorDefault() returns the default color of the axes in a
++ 2D viewport.

axesColorDefault   : PAL                                -> PAL
++ axesColorDefault(p) sets the default color of the axes in a 2D
++ viewport to the palette p.

unitsColorDefault  : ()                                -> PAL
++ unitsColorDefault() returns the default color of the unit ticks in
++ a 2D viewport.

unitsColorDefault  : PAL                                -> PAL

```

```

    ++ unitsColorDefault(p) sets the default color of the unit ticks in
    ++ a 2D viewport to the palette p.

pointSizeDefault    : ()                                -> PI
    ++ pointSizeDefault() returns the default size of the points in
    ++ a 2D viewport.

pointSizeDefault    : PI                                -> PI
    ++ pointSizeDefault(i) sets the default size of the points in a 2D
    ++ viewport to i.

viewPosDefault      : () -> L NNI
    ++ viewPosDefault() returns the default x and y position of a
    ++ viewport window unless overridden explicitly, newly created
    ++ viewports will have this x and y coordinate.

viewPosDefault      : L NNI -> L NNI
    ++ viewPosDefault([x,y]) sets the default x and y position of a
    ++ viewport window unless overridden explicitly, newly created
    ++ viewports will have the x and y coordinates x, y.

viewSizeDefault     : () -> L PI
    ++ viewSizeDefault() returns the default viewport width and height.

viewSizeDefault     : L PI -> L PI
    ++ viewSizeDefault([w,h]) sets the default viewport width to w and height
    ++ to h.

viewDefaults        : ()                                -> Void
    ++ viewDefaults() resets all the default graphics settings.

viewWriteDefault    : ()                                -> L S
    ++ viewWriteDefault() returns the list of things to write in a viewport
    ++ data file; a viewalone file is always generated.

viewWriteDefault    : L S                                -> L S
    ++ viewWriteDefault(l) sets the default list of things to write in a
    ++ viewport data file to the strings in l; a viewalone file is always
    ++ generated.

viewWriteAvailable  : ()                                -> L S
    ++ viewWriteAvailable() returns a list of available methods for writing,
    ++ such as BITMAP, POSTSCRIPT, etc.

var1StepsDefault    : () -> PI
    ++ var1StepsDefault() is the current setting for the number of steps to
    ++ take when creating a 3D mesh in the direction of the first defined
    ++ free variable (a free variable is considered defined when its
    ++ range is specified (e.g. x=0..10)).

```

```

var2StepsDefault      : () -> PI
  ++ var2StepsDefault() is the current setting for the number of steps to
  ++ take when creating a 3D mesh in the direction of the first defined
  ++ free variable (a free variable is considered defined when its
  ++ range is specified (e.g. x=0..10)).

var1StepsDefault      : PI -> PI
  ++ var1StepsDefault(i) sets the number of steps to take when creating a
  ++ 3D mesh in the direction of the first defined free variable to i
  ++ (a free variable is considered defined when its range is specified
  ++ (e.g. x=0..10)).

var2StepsDefault      : PI -> PI
  ++ var2StepsDefault(i) sets the number of steps to take when creating a
  ++ 3D mesh in the direction of the first defined free variable to i
  ++ (a free variable is considered defined when its range is specified
  ++ (e.g. x=0..10)).

tubePointsDefault    : PI -> PI
  ++ tubePointsDefault(i) sets the number of points to use when creating
  ++ the circle to be used in creating a 3D tube plot to i.

tubePointsDefault    : () -> PI
  ++ tubePointsDefault() returns the number of points to be used when
  ++ creating the circle to be used in creating a 3D tube plot.

tubeRadiusDefault    : Float -> SF -- current tube.spad asks for SF
  ++ tubeRadiusDefault(r) sets the default radius for a 3D tube plot to r.

tubeRadiusDefault    : () -> SF
  ++ tubeRadiusDefault() returns the radius used for a 3D tube plot.

WeierstrassPreparation examples

=====

This package implements the Weierstrass preparation theorem for multivariate power series.

`weierstrass(v,p)` where `v` is a variable, and `p` is a `TaylorSeries(R)` in which the terms of lowest degree `s` must include `c*v**s` where `c` is a constant, `s>0`, is a list of `TaylorSeries` coefficients `A[i]` of the equivalent polynomial

$$A = A[0] + A[1]*v + A[2]*v**2 + \dots + A[s-1]*v**(s-1) + v**s$$

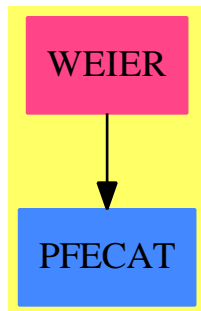

such that  $p=A*B$ , `B` being a `TaylorSeries` of minimum degree 0

### package ZDSOLVE ZeroDimensionalSolvePackage

Based on triangular decompositions and the **RealClosure** constructor, the package **ZeroDimensionalSolvePackage** provides operations for computing symbolically the real or complex roots of polynomial systems with finitely many solutions.

— **ZeroDimensionalSolvePackage.input** —

```

```
=====
ZeroDimensionalSolvePackage examples
=====
```

A package for computing symbolically the complex and real roots of zero-dimensional algebraic systems over the integer or rational numbers. Complex roots are given by means of univariate representations of irreducible regular chains. Real roots are given by means of tuples of coordinates lying in the RealClosure of the coefficient ring.

This constructor takes three arguments. The first one `R` is the coefficient ring. The second one `ls` is the list of variables involved in the systems to solve. The third one must be `concat(ls,s)` where `s` is an additional symbol used for the univariate representations.

WARNING. The third argument is not checked.

All operations are based on triangular decompositions. The default is to compute these decompositions directly from the input system by using the `RegularChain` domain constructor.

The `lexTriangular` algorithm can also be used for computing these decompositions (see `LexTriangularPackage` package constructor).

For that purpose, the operations `univariateSolve`, `realSolve` and `positiveSolve` admit an optional argument.

The `ZeroDimensionalSolvePackage` package constructor provides operations for computing symbolically the complex or real roots of zero-dimensional algebraic systems.

The package provides no multiplicity information (i.e. some returned roots may be double or higher) but only distinct roots are returned.

Complex roots are given by means of univariate representations of irreducible regular chains. These representations are computed by the `univariateSolve` operation (by calling the `InternalRationalUnivariateRepresentationPackage` package constructor which does the job).

Real roots are given by means of tuples of coordinates lying in the `RealClosure` of the coefficient ring. They are computed by the `realSolve` and `positiveSolve` operations. The former computes all the solutions of the input system with real coordinates whereas the later concentrate on the solutions with (strictly) positive coordinates. In

both cases, the computations are performed by the RealClosure constructor.

Both computations of complex roots and real roots rely on triangular decompositions. These decompositions can be computed in two different ways. First, by applying the zeroSetSplit operation from the REGSET domain constructor. In that case, no Groebner bases are computed. This strategy is used by default. Secondly, by applying the zeroSetSplit from LEXTRIPK. To use this later strategy with the operations univariateSolve, realSolve and positiveSolve one just needs to use an extra boolean argument.

Note that the way of understanding triangular decompositions is detailed in the example of the RegularTriangularSet constructor.

The ZeroDimensionalSolvePackage constructor takes three arguments. The first one R is the coefficient ring; it must belong to the categories OrderedRing, EuclideanDomain, CharacteristicZero and RealConstant. This means essentially that R is Integer or Fraction(Integer). The second argument ls is the list of variables involved in the systems to solve. The third one MUST BE concat(ls,s) where s is an additional symbol used for the univariate representations. The abbreviation for ZeroDimensionalSolvePackage is ZDSOLVE.

We illustrate now how to use the constructor ZDSOLVE by two examples: the Arnborg and Lazard system and the L-3 system (Aubry and Moreno Maza). Note that the use of this package is also demonstrated in the example of the LexTriangularPackage constructor.

Define the coefficient ring.

```
R := Integer
Integer
Type: Domain
```

Define the lists of variables:

```
ls : List Symbol := [x,y,z,t]
[x,y,z,t]
Type: List Symbol
```

and:

```
ls2 : List Symbol := [x,y,z,t,new()$Symbol]
[x,y,z,t,%A]
Type: List Symbol
```

Call the package:

```
pack := ZDSOLVE(R,ls,ls2)
ZeroDimensionalSolvePackage(Integer,[x,y,z,t],[x,y,z,t,%A])
```

Type: Domain

Define a polynomial system (Arnborg-Lazard)

```
p1 := x**2*y*z + x*y**2*z + x*y*z**2 + x*y*z + x*y + x*z + y*z
      2      2      2
      x y z + (x y + (x + x + 1)y + x)z + x y
Type: Polynomial Integer
```

```
p2 := x**2*y**2*z + x*y**2*z**2 + x**2*y*z + x*y*z + y*z + x + z
      2 2      2 2      2
      x y z + (x y + (x + x + 1)y + 1)z + x
Type: Polynomial Integer
```

```
p3 := x**2*y**2*z**2 + x**2*y**2*z + x*y**2*z + x*y*z + x*z + z + 1
      2 2 2      2      2
      x y z + ((x + x)y + x y + x + 1)z + 1
Type: Polynomial Integer
```

```
lp := [p1, p2, p3]
      2      2      2
[x y z + (x y + (x + x + 1)y + x)z + x y,
      2 2      2 2      2
      x y z + (x y + (x + x + 1)y + 1)z + x,
      2 2 2      2      2
      x y z + ((x + x)y + x y + x + 1)z + 1]
Type: List Polynomial Integer
```

Note that these polynomials do not involve the variable  $t$ ; we will use it in the second example.

First compute a decomposition into regular chains (i.e. regular triangular sets).

```
triangSolve(lp)$pack
[

]

```

Type: List RegularChain(Integer,[x,y,z,t])

We can see easily from this decomposition (consisting of a single regular chain) that the input system has 20 complex roots.

Then we compute a univariate representation of this regular chain.

```

```

Type: List List RealClosure Fraction Integer

The number of real solutions for the input system is:

```

# lr
8

```

Type: PositiveInteger

Each of these real solutions is given by a list of elements in RealClosure(R). In these 8 lists, the first element is a value of z, the second of y and the last of x. This is logical since by setting the list of variables of the package to [x,y,z,t] we mean that the elimination ordering on the variables is t < z < y < x. Note that each system treated by the ZDSOLVE package constructor needs only to be zero-dimensional w.r.t. the variables involved in the system it-self and not necessarily w.r.t. all the variables used to define the package.

We can approximate these real numbers as follows. This computation

takes between 30 sec. and 5 min, depending on your machine.

```
[ [approximate(r,1/1000000) for r in point] for point in lr]

```

Type: List List Fraction Integer

We can also concentrate on the solutions with real (strictly) positive coordinates:

```

lpr := positiveSolve(lp)$pack
[]

```

Type: List List RealClosure Fraction Integer

Thus we have checked that the input system has no solution with strictly positive coordinates.

Let us define another polynomial system (L-3).

```

f0 := x**3 + y + z + t - 1
      3
z + y + x + t - 1

```

Type: Polynomial Integer

```

f1 := x + y**3 + z + t - 1
      3

```

$z + y + x + t - 1$   
 Type: Polynomial Integer

f2 :=  $x + y + z^3 + t - 1$   
 $z^3 + y + x + t - 1$   
 Type: Polynomial Integer

f3 :=  $x + y + z + t^3 - 1$   
 $z + y + x + t^3 - 1$   
 Type: Polynomial Integer

lf := [f0, f1, f2, f3]  
 $[z^3 + y + x + t - 1, z^3 + y + x + t - 1, z^3 + y + x + t - 1, z^3 + y + x + t - 1]$   
 Type: List Polynomial Integer

First compute a decomposition into regular chains (i.e. regular triangular sets).

lts := triangSolve(lf)\$pack

Type: List Record(complexRoots: SparseUnivariatePolynomial Integer,
coordinates: List Polynomial Integer)

```

Note that this computation is made from the input system lf.

However it is possible to reuse a pre-computed regular chain as follows:

```

ts := lts.1
      2      3      3
      {t + t + 1, z - z - t + t,

      3      2      2      3      6      3      3      2
      (3z + 3t - 3)y + (3z + (6t - 6)z + 3t - 6t + 3)y + (3t - 3)z
+

```

```

      6      3      9      6      3
      (3t  - 6t  + 3)z + t  - 3t  + 5t  - 3t
    ,
    x + y + z}
      Type: RegularChain(Integer, [x,y,z,t])

univariateSolve(ts)$pack

      3      3      3      3      3
Type: List List RealClosure Fraction Integer

```

The number of real solutions for the input system is:

```

#lr2
27
Type: PositiveInteger

```

Another example of computation of real solutions illustrates the `LexTriangularPackage` package constructor.

We concentrate now on the solutions with real (strictly) positive coordinates:

```

lpr2 := positiveSolve(lf)$pack
      1      3      1      1      3      1      1      3      1
[[[%B40,- - %B40 + -,- - %B40 + -,- - %B40 + -]]
      3      3      3      3      3
Type: List List RealClosure Fraction Integer

```

Finally, we approximate the coordinates of this point with 20 exact digits:

```

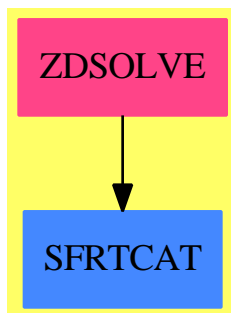

[approximate(r,1/10**21)::Float for r in lpr2.1]
[0.3221853546 2608559291, 0.3221853546 2608559291, 0.3221853546 2608559291,
0.3221853546 2608559291]

```

Type: List Float

**ZeroDimensionalSolvePackage (ZDSOLVE)****Exports:**

convert positiveSolve realSolve squareFree triangSolve univariateSolve

— package ZDSOLVE ZeroDimensionalSolvePackage —

```

)abbrev package ZDSOLVE ZeroDimensionalSolvePackage
++ Author: Marc Moreno Maza
++ Date Created: 23/01/1999
++ Date Last Updated: 08/02/1999
++ Description:
++ A package for computing symbolically the complex and real roots of
++ zero-dimensional algebraic systems over the integer or rational
++ numbers. Complex roots are given by means of univariate representations
++ of irreducible regular chains. Real roots are given by means of tuples
++ of coordinates lying in the \spadtype{RealClosure} of the coefficient ring.
++ This constructor takes three arguments. The first one \spad{R} is the
++ coefficient ring. The second one \spad{ls} is the list of variables
++ involved in the systems to solve. The third one must be \spad{concat(ls,s)}
++ where \spad{s} is an additional symbol used for the univariate
++ representations.
++ WARNING. The third argument is not checked.
++ All operations are based on triangular decompositions.
++ The default is to compute these decompositions directly from the input
++ system by using the \spadtype{RegularChain} domain constructor.
  
```

```

++ The lexTriangular algorithm can also be used for computing these
++ decompositions (see \spadtype{LexTriangularPackage} package constructor).
++ For that purpose, the operations univariateSolve, realSolve and
++ positiveSolve admit an optional argument.

```

```

**Abstract:** A four-parameter fit is developed for the class of integrals known as the exponential integral (real branch). Unlike other fits that are piecewise in nature, the current fit to the exponential integral is valid over the complete domain of the function (compact) and is everywhere accurate to within  $\pm 0.0052\%$  when evaluating the first exponential integral,  $E_1$ . To achieve this result, a methodology that makes use of analytically known limiting behaviors at either extreme of the domain is employed. Because the fit accurately captures limiting behaviors of the  $E_1$  function, more accuracy is retained when the fit is used as part of the scheme to evaluate higher-order exponential integrals,  $E_n$ , as compared with the use of brute-force fits to  $E_1$ , which fail to accurately model limiting behaviors. Furthermore, because the fit is compact, no special accommodations are required (as in the case of spliced piecewise fits) to smooth the value, slope, and higher derivatives in the transition region between two piecewise domains. The general methodology employed to develop this fit is outlined, since it may be used for other problems as well.
